# FINANCIAL INSTABILITY, TAX POLICY, AND THE TAX EXPENDITURE CONCEPT

Tim Edgar\*

## ABSTRACT

*As a public policy goal, moderation of financial instability has gained some prominence in the face of the recent credit contraction. Not surprisingly perhaps, the role of the tax system in exacerbating instances of financial instability has begun to receive some attention in the tax-policy literature. Consistent with the general thrust of that literature, this article explores, in a very preliminary way, how some selected tax-base rule choices line up with an explicit goal of ensuring that the tax system supports regulatory and monetary policies intended to moderate financial instability. The article frames the inquiry in terms of Hyman Minsky's "financial instability hypothesis" as an explanation of the sources of financial instability. Minsky's work suggests how excessive leverage and risk taking arise and can be seen as defensible targets informing the choice of certain tax-base rules, many of which are conventionally characterized in the tax-policy literature as efficiency-reducing concessions to revenue concerns. In this respect, the article draws on tax-expenditure analysis to re-conceptualize the possible design of some of these familiar income base rules whose justification is altered somewhat when framed against Minsky's explanation of the sources of financial instability.*

*More particularly, the article reviews the incomplete manner in which dividend imputation systems commonly address a tax bias in favor of corporate debt, and how this incompleteness can be justified as a means to promote maintenance of margins of safety. The article also reviews the case for and design of loss limitations as applied to financial instruments, as well as restrictions on the deduction of interest expense under the personal income tax as a form of loss limitation. No claim is made to definitively resolve any of these base design issues; nor is there a complete canvassing of all of the possible issues whose resolution is potentially affected by a focus on financial instability. The purpose of the article is the much more modest one of suggesting how standard analyses of interest deductibility and the treatment of losses might be reframed with moderation of financial instability as a public policy goal.*

## I. INTRODUCTION

It is now somewhat trite to observe that the recent credit contraction is the most significant financial crisis since the Great Depression of the 1930s. But this financial crisis is only the latest installment (albeit the most severe) in a series occurring over the past 25 years, including:<sup>1</sup>

- the savings and loan implosion in the United States;
- the stock market crash of 1987;
- the bursting of the Japanese real estate and stock market bubbles;
- the Nordic banking crises of the early 1990s;
- the Asian financial crisis;
- the bailout of the hedge fund, Long-Term Capital Management, in the face of the financial market turmoil occasioned by the default of the Russian government on its ruble-denominated debt; and
- the bursting of the technology share bubble.

The wild boom and bust swings characteristic of capital markets during this relatively brief period appear to have provoked renewed interest in the causes of asset price bubbles<sup>2</sup> and business cycles,<sup>3</sup> with the latter believed by many, until recently at least, to have been eliminated

---

<sup>1</sup> For a detailed historical account of financial crises, see CHARLES P. KINDLEBERGER & ROBERT ALIBER, *MANIAS, PANICS, AND CRASHES: A HISTORY OF FINANCIAL CRISES* (5<sup>th</sup> ed., 2005). See also CARMEN M. REINHART & KENNETH S. ROGOFF, *THIS TIME IS DIFFERENT: EIGHT CENTURIES OF FINANCIAL FOLLY* (2009); and FRANKLIN ALLEN & DOUGLAS GALE, *UNDERSTANDING FINANCIAL CRISES* 1-26 (2007).

<sup>2</sup> See KINDLEBERGER & ALIBER, *supra* note 1, at 1 (“...; by definition a bubble involves a non-sustainable pattern of price changes or cash flows.”).

<sup>3</sup> See e.g., Yair Listokin, *Stabilizing the Economy Through the Income Tax Code*, 123 TAX NOTES 1575, 1575 (2009) (noting renewed interest in the use of the tax system as a policy instrument to stabilize the economy).

by continued growth supported by monetary policy focused on wage and consumer price inflation. The contraction of the global credit system triggered by the bursting of the housing bubble in the United States has also highlighted what was already an emerging reexamination of the intellectual framework of orthodox financial economics.<sup>4</sup>

The role of tax policy in all of this financial market mayhem is beginning to attract some attention. For example, the International Monetary Fund (“the IMF”) recently released a thoughtful and detailed paper exploring the possible relationship between the tax system and financial instability.<sup>5</sup> The IMF paper’s principal points of emphasis are the well-known tax bias

TAX J. 387 (2009). Two academic workshops on the relationship

in favor of corporate debt, as well as tax preferences for housing. There is also some discussion of the possible effects of tax preferences for managerial compensation, loss limitations and risk taking, and tax-driven financial innovation, particularly in the cross-border context. The IMF paper emphasizes that, at the macro level, tax is probably of secondary importance in any attempt to realize a rough balance between financial stability and economic growth. This secondary role is suggested most obviously by the fact that the tax biases identified as possibly contributing to financial instability have been part of tax systems for some time and probably cannot be seen as precipitating the latest crisis (or even the series of crises over the past 25 years).<sup>6</sup> Nonetheless, because of its magnitude, this latest financial crisis brings into sharper focus the need for tax rules that can be seen to support regulatory and monetary policy in the sense that any behavioral responses do not exacerbate financial instability.<sup>7</sup> With this secondary role in mind, the IMF paper tentatively supports measures that attempt to realize consistency of treatment along certain behavioral margins. The suggestions tend to be broadly consistent with familiar arguments for reform in the various areas highlighted in the IMF paper. Indeed, these arguments are entirely independent of maintenance of financial stability as a public policy goal.

---

between tax policy and the financial crisis have also been held recently. *See* TAX POLICY AND THE FINANCIAL CRISIS (Apr. 30, 2009) ECONPUBBLICA, Center for Research on the Economics of the Public Sector, Università Commerciale Luigi Bocconi, Milan; and RETHINKING THE TAXATION OF THE FINANCIAL SECTOR IN THE LIGHT OF THE RECENT CRISIS (Feb. 5, 2010) New York University School of Law, Office of Tax Policy Research, Ross School of Business, University of Michigan, and University of North Carolina Tax Center, <http://www.bus.umich.edu/Conferences/Taxation-of-the-Financial-Sector>.

<sup>6</sup> *See e.g.*, Hemmelgarn & Nicodeme, *supra* note 5, at 2 (“While taxes have not generated the crisis, some aspects of tax policy may have led to increased risk-taking and indebtedness of banks, households and companies.”); Lloyd, *supra* note 5, at 17 (“... taxes were not the root cause of the financial crisis, but tax rules for individuals and corporates may have encouraged financial instability through encouraging risk-taking, risky credit and corporate leverage, and through a lack of transparency facilitated by tax havens.”); and Shaviro, *Financial Crisis*, *supra* note 5, at 3 (observing that any causal relationship between tax policy and the recent credit crisis remains unclear). *But see* Martin A. Sullivan, *Deleveraging the Tax Code*, 120 TAX NOTES 1241 (2008) (emphasizing a close link between interest deductibility for income tax purposes and levels of leverage).

This article similarly explores how some selected aspects of tax policy line up with an explicit goal of ensuring that the tax system supports regulatory and monetary policies intended to moderate financial instability. The article differs, however, from the IMF paper, as well as the other limited literature on the same subject,<sup>8</sup> in two respects. First, it frames the inquiry explicitly in terms of a theoretical perspective that attempts to explain the sources of financial instability. Second, the discussion draws on the tax-expenditure concept and tax-expenditure analysis to reconceptualize the design of some familiar income base rules whose justification is altered somewhat when framed against this particular explanation of the sources of financial instability.

Part II begins, therefore, with a brief description of Hyman Minsky's financial instability hypothesis,<sup>9</sup> which explains how excessive leverage and risk taking arise; as the sources of financial instability, they can be seen as defensible targets informing the choice of certain tax-base rules, many of which are characterized in the tax-policy literature as efficiency-reducing concessions to revenue concerns. Part III then attempts to advance this suggestion at a broad conceptual level by reviewing some familiar ground covered in the tax-expenditure literature. It is argued that the tax-expenditure concept can usefully frame the assessment of various tax rules as prone to excessive leverage and risk taking. Tax-expenditure analysis can be invoked to supplement standard technical tax-policy analyses of these provisions once they are framed in this much different manner.

---

<sup>7</sup> Shaviro, *Financial Crisis*, *supra* note 5 (emphasizing the need for tax rules to avoid behavioral responses that exacerbate the causes of financial crises).

<sup>8</sup> *See supra* note 5.

<sup>9</sup> Minsky's financial instability hypothesis is articulated most completely in HYMAN P. MINSKY, *STABILIZING AN UNSTABLE ECONOMY* (1986) [hereinafter MINSKY, *STABILIZING*]. With the first edition out of print, recent interest in Minsky's ideas led to publication of a second edition (2008), posthumously, under the guidance of Dimitri B. Papadimitriou and L. Randall Wray, two former colleagues of Minsky's at the Levy Economics Institute. Much of the earlier development of the financial instability hypothesis is found in HYMAN P. MINSKY, JOHN MAYNARD KEYNES (1975).

At a macro level, the tax-policy literature tends to highlight the use of a progressive personal income tax and broad-based consumption taxes as automatic stabilizers.<sup>10</sup> Consistent with the IMF paper, Parts IV and V go further and examine some fundamental tax-base rule choices with a view to moderating financial instability. Part IV reviews the tax bias in favor of corporate debt and, more particularly, how the incomplete manner in which dividend imputation systems commonly address this bias can be justified as a means to promote maintenance of margins of safety. Part V examines the case for and design of loss limitations as applied to financial instruments, as well as restrictions on the deduction of interest expense under the personal income tax as a form of loss limitation. The article makes no claim to resolve any of these particular base design issues; its purpose is the much more modest one of suggesting, in a very preliminary way, how standard analyses of interest deductibility and the treatment of losses might be reframed with moderation of financial instability as a public policy goal.

Given this modest aim, the review of the income base design issues in the last two parts is necessarily incomplete.<sup>11</sup> Perhaps most importantly, there is no discussion of issues unique to

<sup>10</sup> See e.g., Christian E. Weller & Manita Rao, *Can Progressive Taxation Contribute to Economic Development?* (Political Economy Research Institute, Univ. of Massachusetts, Working Paper Series No. 176, July 2008), available at <http://ssrn.com/abstract=1298636> (finding a link between progressive personal income taxation and economic stability through an ability to conduct counter-cyclical fiscal policies). For a review of the empirical literature on the relationship between fiscal policy, business cycles, and stabilization, see Young Lee & Taeyoon Sung, *Fiscal Policy, Business Cycles and Economic Stabilisation: Evidence from Industrialised and Developing Countries*, 28 FISCAL STUDIES 437, 439-41 (2007) (finding from a data set of 94 countries that government current expenditures, subsidies, and transfers move counter-cyclically, whereas taxes and capital expenditures move pro-cyclically). See also Listokin, *supra* note 3, at 1578-80 (observing that the counter-cyclical effect of a progressive personal income tax rate structure can be enhanced by indexation to the rate of economic growth); and Yair Jason Listokin, *Tax Expenditures and Business Cycle Fluctuations* (John M. Olin Center for Studies in Law, Economics, and Public Policy, Research Paper No. 378, Apr. 2009), available at <http://ssrn.com/abstract=1372782> (emphasizing the pro-cyclical nature of some tax expenditures).

<sup>11</sup> For a more complete canvassing of the possible tax-policy issues whose resolution is potentially affected by a focus on moderation of financial instability, see IMF, CRISIS-RELATED ISSUES, *supra* note 5; Hemmelgarn & Nicodeme, *supra* note 5; Keen, Klemm, & Perry, *supra* note 5; Lloyd, *supra* note 5; and Shaviro, *Financial Crisis*, *supra* note 5. See also Martin A. Sullivan, *10 Tax Changes to Prevent the Next*

the financial sector.<sup>12</sup> Parts IV and V note only in passing how some of the rule choices applied on the demand side of capital markets might be modified when applied on the supply side: that is, the financial services sector. There is similarly no discussion of: (i) the effect on risk taking of the provision of preferential tax rates for managerial compensation;<sup>13</sup> or (ii) the use of a transactions tax to moderate financial instability.<sup>14</sup> Adequate discussion of any of these subjects,

---

*Fiscal Crisis*, 124 TAX NOTES 1295 (2009) [hereinafter Sullivan, *10 Changes*] (briefly describing a set of tax-reform measures intended to moderate financial instability).

<sup>12</sup> See e.g., Shackelford, Shaviro, & Slemrod, *supra* note 5, at 6-15 (discussing the theory and design of corrective taxes as applied to the financial sector). See also Jaime Caruana, General Manager of the Bank for International Settlements (BIS), *The International Policy Responses to Financial Crises: Making the Macroprudential Approach Operational - Panel Remarks*, Jackson Hole (Aug. 21-22, 2009), available at <http://www.bis.org/speeches/sp090911.htm>; Tobias Adrian & Markus Brunnermeier, *CoVAR* (Federal Reserve Bank of New York Staff Reports, No. 348, Aug. 27, 2009), available at <http://ssrn.com/abstract=1269446>; and Viral V. Acharya, Lasse H. Pedersen, Thomas Philippon, & Matthew Richardson, *Regulating Systemic Risk*, in RESTORING FINANCIAL STABILITY: HOW TO REPAIR A FAILED SYSTEM 283 (Viral V. Acharya & Matthew Richardson eds., 2009) (suggesting the use of a capital charge as a corrective tax capturing the marginal contribution of individual financial institutions to system-wide risk). A “financial activities tax,” levied on the sum of profits and remuneration of financial institutions, is suggested in INT’L MONETARY FUND, A FAIR AND SUBSTANTIAL CONTRIBUTION BY THE FINANCIAL SECTOR (June, 2010), available at <http://www.itdweb.org/documents/.../IMF>. H.R. 4173 IH proposes the adoption of a tax on wholesale liabilities of large financial institutions as a means to recover some of the cost of the provision of liquidity and capital insurance by the US government. See Lee A. Sheppard & Martin A. Sullivan, *Taxing Financial Pollution*, 126 TAX NOTES 697 (2010).

<sup>13</sup> See IMF, CRISIS-RELATED ISSUES, *supra* note 5, at 29-31 (highlighting deferred taxation of executive stock options and capital gains treatment of the return to the carried interests of fund managers as the two principal forms of tax-preferred managerial compensation which may affect risk taking). See also Shaviro, *Financial Crisis*, *supra* note 5, at 20 (suggesting that the tax system should disfavor poorly designed incentive arrangements). *But see* Rudiger Fahlenbrach & Rene M. Stulz, *Bank CEO Incentives and the Credit Crisis* (Charles A. Dice Center Working Paper No. 2009-13, July 2009), available at <http://ssrn.com/abstract=1439859> (finding: (i) no evidence that alignment of managerial incentives with the interests of shareholders resulted in better bank performance during the credit crisis; and (ii) option compensation did not have an adverse impact on performance). France and the United Kingdom recently adopted temporary taxes on bonus payments to financial sector employees. See Shackelford, Shaviro, & Slemrod, *supra* note 5, at 17-18.

<sup>14</sup> See e.g., Adam H. Rosenzweig, *Imperfect Financial Markets and the Hidden Costs of a Modern Income Tax*, 62 SMU L. REV. 239 (2009) (proposing the application of a transactions tax to derivative financial

with moderation of financial instability as a policy goal, warrants separate treatment. Finally, the subject of tax avoidance is largely ignored.<sup>15</sup> The unique issue in this area is the relationship, if any, between risk taking and tax-avoidance activity. This also appears to be a subject that requires separate treatment, primarily as an empirical inquiry.<sup>16</sup> It is possible, however, that the broad conceptual framework described in the article can usefully frame the discussion of these other issues in much the same way that it does the tax-base rule choices reviewed in Parts IV and V.

## II. MINSKY'S FINANCIAL INSTABILITY HYPOTHESIS AND THE MISMEASUREMENT OF RISK

Minsky's financial instability hypothesis emphasizes the role of leverage as the source of persistent financial instability in sophisticated market economies. The instability may be exacerbated by the development of a broad range of derivative financial instruments, as well as fundamental weaknesses of finance theory that have led to the mismeasurement of risk. This

---

instruments to dampen increased counterparty default risk in the presence of the scaling up of bets associated with such instruments to eliminate the effect of income taxation). There is a deep literature on the design of financial transaction taxes as a policy instrument to dampen excessive volatility in commodities and securities markets. This literature is surveyed in Thornton Matheson, *Taxing Financial Transactions: Issues and Evidence* (IMF Working Paper WP/10/\*\*, June 2010), available at <http://www-bec.imf.org/external/pubs/ft/wp/2010> See also Hemmelgarn & Gale, *supra* note 5, at 27-35 (concluding that the effects of a financial transactions tax on asset price bubbles are ambiguous and preferring elimination of the preferential treatment of debt as a more promising means to avoid excessive leverage and risk taking).

<sup>15</sup> There is some limited discussion of tax planning along the debt-equity boundary when interest and dividends are treated inconsistently for a range of investors. See *infra* notes 161-67, and accompanying text.

<sup>16</sup> IMF, CRISIS-RELATED ISSUES, *supra* note 5, at 25-28 (noting the lack of understanding of the effect of tax-driven financial innovation, including securitization, as well as the use of low-tax jurisdictions in cross-border tax planning). The growing empirical literature on corporate governance and tax sheltering would appear to suggest a weak link between tax avoidance and risk taking. See DANIEL N. SHAVIRO, *DECODING THE U.S. CORPORATE INCOME TAX*, 174-78 (2009) [hereinafter Shaviro, *DECODING*] (briefly reviewing some of the relevant literature). *But see also* Eddins, *supra* note 5 (characterizing securitization and credit default swaps as tax-driven transactions requiring the creation of low-quality mortgages with systemic risk implications); and Hemmelgarn & Gale, *supra* note 5, at 26 (characterizing Eddins's tax arbitrage feedback theory as "a seducing and rather convincing theory" that requires empirical testing).

broader economic framework highlights the significance of excessive risk taking attributable to excessive leverage and the mismeasurement of risk as sources of default risk and the associated systemic risk. On the assumption of an optimal allocation of resources in the absence of the change in price occasioned by the imposition of taxes, tax policymakers have ignored these effects while focusing on micro-level incentives. At a macro level, these incentives can exacerbate the effect of nontax factors as causes of financial instability, with potential costs for the economy that are borne, in part, by innocent third parties. In this respect, excessive leverage and risk taking, at a macro level, can be viewed as a negative externality.<sup>17</sup>

#### A. FINANCIAL STABILITY AS A PUBLIC POLICY GOAL AND LEVERAGE AS A SOURCE OF FINANCIAL INSTABILITY

Because a focus on maintenance of financial stability as a public policy goal would seem to require a working definition of the concept,<sup>18</sup> it is perhaps surprising that the content of this concept has not been articulated with any precision; like the corresponding concept of price stability, it may inevitably be somewhat flexible.<sup>19</sup> This characteristic is evident, for example, in one of the more thorough attempts to define financial stability, provided by Allen and Wood,<sup>20</sup> who also canvass various policy instruments that can be used to promote financial stability. They begin the definitional exercise by noting that public policy interest in financial stability reflects

---

<sup>17</sup> See IMF, CIRSIS-RELATED ISSUES, *supra* note 5, at 12 (characterizing excessive leverage as a negative externality that is not captured by micro-economic models focused on the level of firm-specific borrowing as a function of the internalization of bankruptcy costs).

<sup>18</sup> See William A. Allen & Geoffrey Wood, *Defining and Achieving Financial Stability*, 2 J. FINANCIAL STABILITY 152, 152 (2006) (noting the lack of a widely accepted definition of financial stability and the lack of any associated consensus regarding the policies that should be pursued to promote financial stability).

<sup>19</sup> *But see* Allen & Wood, *supra* note 18, at 153 (arguing that, despite differences regarding some of the details of the concept of price stability, there is considerable common ground which is reflected in a clarity of objective and similarity of policies that is not the case with financial stability).

<sup>20</sup> *Id.* See also Garry J. Schinasi, *Defining Financial Stability* (IMF Working Paper WP/04/187, October 2004), available at <http://www-bec.imf.org/external/pubs/ft/wp/2004/wp04/87.pdf> .

an awareness of the negative social and economic consequences associated with an episode of financial instability. They argue that it is useful to think of financial stability as a property of a system much like that in the physical sciences. A financially stable economy is said to be one that “does not degenerate into instability when it experiences ... an unexpected event or shock ... or the unexpected failure of a substantial company.”<sup>21</sup> Allen and Wood then canvass possible characteristic features of an episode of financial instability, which they define as:<sup>22</sup>

“episodes in which a large number of parties, whether they are households, companies, or (individual) governments, experience financial crises which are not warranted by their previous behavior, and where these crises collectively have seriously adverse macro-economic effects.”

For households, businesses, and governments, a financial crisis occurs when access to funds is curtailed such that spending plans must be curtailed. But financial instability at a micro level does not mean that an economy experiences an episode of financial instability at a macro level. At some admittedly ill-defined point, the extent of individual crises becomes so pervasive that innocent bystanders get hurt.<sup>23</sup> Moreover, as Allen and Wood recognize, financial stability as a property of an economy is not completely observable, because an episode of financial instability can be latent and policymakers cannot be certain that the economy will be able to dampen rather than amplify a shock that precipitates a crisis. Given these circumstances, the best that policymakers can do is to monitor “certain crucial features of an economy ... and to draw inferences from such monitoring about the financial stability of an economy.”<sup>24</sup> This necessary monitoring function is arguably performed most effectively when policymakers have an adequate

---

<sup>21</sup> *Id.* at 155. *See also* Schinasi, *supra* note 22, at 8 (“A financial system is in a range of stability whenever it is capable of facilitating (rather than impeding) the performance of an economy, and of dissipating financial imbalances that arise endogenously or as a result of significant adverse or unanticipated events.”).

<sup>22</sup> Allen & Wood, *supra* note 18, at 160.

<sup>23</sup> *Id.* at 159-60.

<sup>24</sup> *Id.* at 155.

model capturing the causes of episodes of financial instability. Despite lacking some of the formal features of a model, Minsky's financial instability hypothesis can be seen to serve this function.<sup>25</sup>

The intuition underlying Minsky's financial instability hypothesis is deceptively simple in its description of the financing function. As Minsky emphasizes, his hypothesis is an interpretation of Keynes's classic work, *The General Theory of Employment, Interest, and Money*,<sup>26</sup> but with an emphasis on the debt financing of investment, rather than fluctuations in household demand and savings, as the principal source of instability.<sup>27</sup> At its core, the financial instability hypothesis is a theory of "the impact of debt on system behavior and also incorporates the manner in which debt is validated."<sup>28</sup> As a finance theory of investment, the level of profits is the key determinant of system behavior, since profits validate debt.

---

<sup>25</sup> See GEORGE COOPER, THE ORIGIN OF FINANCIAL CRISES: CENTRAL BANKS, CREDIT BUBBLES AND THE EFFICIENT MARKET FALLACY, 158 (2008) (concluding that policymakers should develop macroeconomic policy using the financial instability hypothesis as the only model adequately explaining financial market behavior). *But see* Elisabetta De Antoni, *The (too?) Optimistic 'Financial Keynesianism' of Hyman Minsky*, available at <http://www.ius.unicas.it/mc2005/papers/deantoni.pdf>, at 23-24 (noting some weaknesses of the financial instability hypothesis and suggesting that Minsky seemed sufficiently aware of them to label his analysis an hypothesis rather than a theory). Kindleberger draws on Minsky's financial instability hypothesis to frame his historical account of financial crises. See KINDLEBERGER & ALIBER, *supra* note 1, at 24-37.

<sup>26</sup> JOHN MAYNARD KEYNES, THE GENERAL THEORY OF EMPLOYMENT, INTEREST, AND MONEY (1936). See De Antoni, *supra* note 25, at 23-25 (contrasting Minsky's emphasis on upward instability with Keynes's focus on a depressed economy).

<sup>27</sup> See De Antoni, *supra* note 25, at 2-5.

<sup>28</sup> Hyman P. Minsky, *The Financial Instability Hypothesis* (The Levy Economics Institute, Working Paper No. 74, 1992), at 6 [hereinafter Minsky, *Financial Instability Hypothesis*].

More particularly, Minsky illustrates how, at the macro level, aggregate profits for each period equal aggregate investment and depend on aggregate spending on investment.<sup>29</sup> At a micro level, he argues that firms must be able to realize a markup over labor costs and will pursue market power to do so. Prices, therefore, have five discrete functions:<sup>30</sup>

- to ensure that a surplus is generated;
- to ensure that some of the surplus accrues to business owners;
- to ensure that the demand price of capital assets is consistent with the supply price;
- to ensure that debt finance commitments can be satisfied; and
- to ensure that resources are allocated to the investment sector.

In a capitalist economy, these functions are discharged in the form of two sets of prices: one for current output and one for capital assets.<sup>31</sup> The price of current output depends on short-run expectations of demand and wage rates. Spending on investment depends on the demand price (the price that a purchaser is willing to pay) and the supply price (the price that a producer is willing to accept) of capital assets. Investment occurs and profits are generated when the demand price of capital assets exceeds the supply price. The latter is a function of the costs of production, which consist primarily of purchase price (costs of labor plus a markup) and financing costs. The former is a function of expectations about future profits. In other words,

---

<sup>29</sup> MINSKY, *STABILIZING*, *supra* note 9, at 157-90. The aggregate amount of profits equals the sum of investment plus consumption out of profits plus the government's deficit and any trade surplus, less savings out of wages. In a simplified model without government deficits, balanced trade, and no savings out of wages, profits equal investment (plus consumption by capitalists, which is negligible). *See e.g.*, De Antoni, *supra* note 25, at 5-13; Dimitri B. Papadimitriou & L. Randall Wray, *Minsky's Analysis of Financial Capitalism* (The Levy Economics Institute, Working Paper No. 275, 1999), at 6-9; and Janelia Tse, *Minsky's Financial Instability Hypothesis*, 4 *OECONOMICUS* 77-81, 79-80 (2001).

<sup>30</sup> MINSKY, *STABILIZING*, *supra* note 9, at 157-90. *See also* Tse, *supra* note 29, at 79.

<sup>31</sup> Tse, *supra* note 29, at 80.

capital asset prices reflect long-run expectations of future profits, but also the borrower's and lender's risk associated with the financing of investment. Borrower's risk is the risk of losing equity with increased levels of borrowing. Lender's risk is the risk of default, which increases with the level of debt financing.

Investment thereby links the price of capital assets with the price of current production. But the uncertainty associated with expectations of future profits and the financing of capital assets with debt makes the economy unstable. Expectations of profits depend on future investment, with realized profits determined by investment. In short, businesses invest now because they expect investment to occur in the future. Financial intermediaries are the critical actors in this process; they receive savings from households which are provided to businesses for production, with a reverse flow of funds moving from businesses to households again through financial intermediaries. The flow of money to businesses occurs as a response to expectations of future profits, while the flow of money from businesses is financed by realized profits. Expectations of profits determine the flow of financing contracts to businesses and the value of those contracts, with the past, present, and future linked by these financial relations. Expectations are validated when realized profits equal or exceed commitments in the financial contracts as the outcome of negotiations between financial intermediaries and businesses. Minsky's description of financial relations is not limited, however, to businesses; it extends to households and governments by way of their ability to borrow on the basis of expectations of future cash flows. Moreover, his description extends to an open-economy setting when businesses, households, and governments borrow internationally.<sup>32</sup>

---

<sup>32</sup> Minsky, *Financial Instability Hypothesis*, *supra* note 28, at 4-5. See also Philip Arestis & Murray Glickman, *Financial Crisis in Southeast Asia: Dispelling Illusion the Minskyan Way*, 26 CAMBR. J. ECON. 237 (2002) (arguing that the sources of instability identified by Minsky are intensified in an open-economy setting); and Jan Kregel, *Managing the Impact of Volatility in International Capital Markets in an Uncertain World* (The Levy Economics Institute, Working Paper No. 558, 2009) (describing the transmission of financial instability through international capital flows and risk-management techniques of multinational banks).

The explanatory power of these essential features of Minsky's financial instability hypothesis is captured in his two theorems. The first theorem holds that the character of the financial relations predominating at any time in an economy determines its financial stability.<sup>33</sup> In this respect, Minsky describes three states of financial relations characteristic of economic units: hedge finance, speculative finance, and Ponzi finance. A hedge finance unit is characterized by an ability to fulfill payment commitments with realized cash flows. Because equity finance provides a margin of safety in the event that realized profits are less than payment commitments under debt contracts, economic units with greater weighted levels of such finance will tend to be hedge finance units. A speculative finance unit is one that can meet its interest and similar income account commitments as they fall due, but cannot repay the amount of its principal repayment obligations and must roll over or refinance its liabilities on maturity. A Ponzi finance unit is one that cannot fulfill its obligations to pay interest or principal as they become due and must borrow against rising asset prices or sell assets to meet these commitments. Equity finance, and the associated margin of safety, is reduced as a Ponzi unit relies on either or both of asset sales and further borrowing. An economy that is dominated by hedge finance units is stable in the sense that it is vulnerable only to external shocks. An economy that is dominated by speculative and Ponzi finance units is unstable in the sense that it is vulnerable to shocks, both internal and external.

Minsky's second theorem holds that capitalist economies tend to move from a financial structure dominated by hedge finance to a structure dominated by speculative and Ponzi finance during periods of prolonged prosperity.<sup>34</sup> The transition occurs as realized profits continue to

---

<sup>33</sup> Minsky, *Financial Instability Hypothesis*, *supra* note 28, at 7-8.

<sup>34</sup> *Ibid.* Much the same process is described by John Geanakoplos as the "leverage cycle." See e.g., John Geanakoplos, *The Leverage Cycle* (Cowles Foundation Discussion Paper No. 1715, July 2009) [hereinafter Geanakoplos, *Leverage Cycle*], available at <http://www.cowles.econ.yale.edu/>. See also Franklin Allen & Douglas Gale, *Bubbles and Crises*, 110 THE ECONOMIC J. 236 (2000) (constructing a simple model in which agency problems associated with leveraged investment in risky assets cause those assets to be priced above their fundamental value in the context of a credit expansion).

validate debt, which increases expectations of future profit levels and investment financed by greater levels of debt.<sup>35</sup> Financial intermediaries are supposed to function as skeptics and prudently dampen the excessive enthusiasm of businesses so that realized profits are more likely to be sufficient to fulfill commitments. But, as Minsky emphasizes, financial intermediaries are profit-seeking enterprises that innovate in their acquisition of assets and marketing of liabilities. In effect, financial intermediaries constantly innovate in their profit-seeking role as “merchants of debt”<sup>36</sup> and tend to fuel the transition to speculative and Ponzi finance during periods of prolonged prosperity. Financial intermediaries and businesses (as well as households) become increasingly confident and downplay the need for margins of safety while increasing the price of capital assets.<sup>37</sup> An ostensibly stable economy is essentially destabilized by its tranquility, as past success leads to expanding credit and the assumption of riskier positions. A “Minsky moment”<sup>38</sup> can occur, for example, when the inevitable inflationary pressures lead monetary authorities to tighten credit and an expansionary credit cycle tips over to a credit contraction phase. Speculative units become Ponzi units, and Ponzi units see their net wealth disappear. Debt deflation follows as financial intermediaries call in debts and tighten the provision of new credit,

---

<sup>35</sup> This process is famously captured by the label “irrational exuberance,” which was used by Alan Greenspan, when he was chairman of the US Federal Reserve Bank in testimony before Congress, to describe the US stock market bubble in the mid-1990s. The label was arguably made that much more famous when Robert Shiller subsequently used it as the title of his book describing the same asset price bubble. See ROBERT J. SHILLER, *IRRATIONAL EXUBERANCE* (1<sup>st</sup> ed., 2000).

<sup>36</sup> Minsky, *Financial Instability Hypothesis*, *supra* note 28, at 6 (“... thus, bankers ... are merchants of debt who strive to innovate in the assets they acquire and the liabilities they market.”).

<sup>37</sup> See REINHART & ROGOFF, *supra* note 1. See also Caruana, *supra* note 12 (emphasizing the feedback effects of credit extension, leverage, risk perceptions and risk appetite, asset prices, and economic activity which together can make the financial system more complex and characterized by nonlinear dynamics); and Geanakoplos, *Leverage Cycle*, *supra* note 34 (emphasizing the significance of reductions in collateral requirements during periods of prosperity which are then increased in a debt deflationary environment).

<sup>38</sup> Minsky never used the term “Minsky moment” to describe the downward shift in a business cycle with the ensuing necessity to sell assets to meet payment commitments. The term was apparently coined by a bond fund director, Paul McCulley, during the Russian debt crisis. See Justin Lahart, *In Time of Tumult, Obscure Economist Gains Currency*, WALL ST. J., August 18, 2007, at A1.

while borrowers must sell assets to fulfill payment commitments. The ensuing collapse of asset values and profits only exacerbates the debt deflation,<sup>39</sup> resulting in increasing bankruptcies, recession, and a depression in the extreme.

## B. DERIVATIVES AND THE MISMEASUREMENT OF RISK AS SOURCES OF FINANCIAL INSTABILITY

In contrast with neo-classical economic theory, Minsky takes seriously the financial intermediation function, which he refers to generically as “banking.”<sup>40</sup> He describes a sophisticated capitalist economy as characterized by expensive capital assets and a sophisticated financial system required for the deployment of such assets. Present money pays for the resources needed for the creation and use of capital assets in production; it is exchanged for liabilities which commit producing units to pay future money in the form of profits at specified dates under specified conditions. Borrowers and lenders expect that profits generated by the capital assets will exceed financing commitments, but because this does not always turn out to be the case, financial stability cannot be taken as an assumed condition.

The dynamics of this financing function, which are described by Minsky as the source of financial instability, do not depend on a premise of irrationality on the part of investors along any behavioral margin.<sup>41</sup> Rather, the instability-breeding characteristics of the market for financial

---

<sup>39</sup> See e.g., E. Philip Davis & Mark R. Stone, *Corporate Financial Structure and Financial Stability*, 1 J. FINANCIAL STABILITY 65 (2004) (finding that the debt-equity ratios of firms are correlated with investment and inventory declines following crises). The process of debt deflation was first described by Irving Fisher, *The Debt Deflation Theory of Great Depressions*, 1 ECONOMETRICA 337 (1933).

<sup>40</sup> MINSKY, STABILIZING, *supra* note 9, at 173 (“In today’s standard economic theory, an abstract non-financial economy is analyzed. Theorems about this abstract economy are assumed to be essentially valid for economies with complex financial and monetary institutions and usages. This logical jump is an act of faith ...”). See also Papadimitriou & Wray, *supra* note 29, at 4-6 (describing the assumptions underlying the orthodox microeconomic and macroeconomic models criticized by Minsky).

<sup>41</sup> See COOPER, *supra* note 25, at 101 (“... financial instability is hard wired into the mechanics of the asset and debt markets; it is therefore unnecessary to resort to the still-contentious arguments of behavioural finance to demonstrate market instability. But this is not to say that behavioural finance should be ignored,

assets are the product of rational responses to market signals, albeit with exacerbating behavioral dynamics attributable to human shortcomings such as cognitive biases and the use of heuristics in decision making under uncertainty.<sup>42</sup> Minsky's challenge to neoclassical orthodoxy can be characterized, therefore, as a fundamental one distinguishing the market for consumer goods and services from the market for financial assets. The pricing mechanism of the former operates to allocate resources. Increased demand for an item triggers an increase in supply and vice versa, with changes in price equating demand and supply such that markets clear. Because of this process, the market for consumer goods and services is equilibrium seeking: That is, it is inherently stable, since only external shocks can move the market pricing mechanism off course into a state of disequilibrium. As emphasized by Minsky's financial instability hypothesis, the market for financial assets is much different in that it is characterized by the search for scarcity value in an environment in which supply does not respond completely to changes in price.<sup>43</sup> An increase in price can stimulate increased demand without a corresponding increase in supply, while a decrease in price can cause a decrease in demand without a contraction of supply. In this

---

as this area can also give rise to powerful positive feedback cycles.”); and Geanakoplos, *Leverage Cycle*, *supra* note 34, at 3 (“But a crucial part of my leverage cycle story is that every agent is acting perfectly rationally from his own individual point of view.”). *See also* ROBERT J. BARBERA, *THE COST OF CAPITALISM: UNDERSTANDING MARKET MAYHEM AND STABILIZING OUR ECONOMIC FUTURE* 186 (2009) (“...behavioral finance ... provides modern day insights that buttress Minsky's financial instability hypothesis. Championing the notion that mainstream theory should embrace important parts of Minsky's thesis, in effect, also amounts to ending the fringe status of behavioral finance.”).

<sup>42</sup> Shiller provides a thorough account of various factors driving the herd mentality that produces the kind of powerful positive feedback effects emphasized by Minsky. *See* Shiller, *supra* note 35; Robert Shiller, *Human Behavior and the Efficiency of the Financial System*, in *HANDBOOK OF MACROECONOMICS* 1 (John B. Taylor & Michael Woodford eds., Vol. 1, 1999); and GEORGE A. AKERLOF & ROBERT J. SHILLER, *ANIMAL SPIRITS: HOW HUMAN PSYCHOLOGY DRIVES THE ECONOMY, AND WHY IT MATTERS FOR GLOBAL CAPITALISM* 11-56, 131-48 (2009). *See also* ANDREI SHLEIFER, *INEFFICIENT MARKETS: AN INTRODUCTION TO BEHAVIORAL FINANCE* (2000).

<sup>43</sup> COOPER, *supra* note 25, at 7-8. *But see also* RICHARD BOOKSTABER, *A DEMON OF OUR OWN DESIGN: MARKETS, HEDGE FUNDS, AND THE PERILS OF FINANCIAL INNOVATION* 213-20 (2007) (emphasizing demand and supply of liquidity as the principal driver of price movements rather than the revelation of information).

type of market, it is the rate of price change that affects demand rather than price change itself;<sup>44</sup> such a market is not equilibrium seeking and is inherently unstable.

Orthodox financial theory has nonetheless tended to ignore these fundamental differences and has largely transplanted the pricing mechanism of the market for consumer goods and services as a conceptual framework for the modeling of the pricing mechanism of the market for financial assets.<sup>45</sup> As expressed in the “efficient market hypothesis,”<sup>46</sup> this orthodoxy posits that at any point in time, the price of particular financial assets incorporates all relevant information – concerning both the present and the future - and is the correct price as determined by the forces of supply and demand. Prices are seen to move in response to new information, and only external shocks can force the market into a state of disequilibrium. Price movements are entirely random, with this characteristic of financial markets providing the conceptual foundation

---

<sup>44</sup> Cooper, *supra* note 25, at 8. *See also* Jack Treynor, *Bulls, Bears, and Market Bubbles*, 54 FINANCIAL ANALYSTS J. 69 (1998) (arguing that investors’ different views mean that there are winners and losers as prices change in response to new information, with the resulting wealth effect creating a new equilibrium and wealth shift that can cause greater subsequent price changes).

<sup>45</sup> For accessible and entertaining accounts of the development of financial theory, see PETER L. BERNSTEIN, *CAPITAL IDEAS: THE IMPROBABLE ORIGINS OF MODERN WALL STREET* (1992); PETER L. BERNSTEIN, *AGAINST THE GODS: THE REMARKABLE STORY OF RISK* (1996); and PETER L. BERNSTEIN, *CAPITAL IDEAS EVOLVING* (2007) [hereinafter BERNSTEIN, *EVOLVING*].

<sup>46</sup> The efficient market hypothesis is the outcome of a deep literature which attempts to explain the apparently random price movements in markets for financial assets and commodities. For a bibliographic, as well as temporal, listing of the various research contributions to the development of the efficient market hypothesis, along with significant contributions to the behavioral finance school of thought, see Martin Sewell, *History of the Efficient Market Hypothesis* (August 2008), available at <http://www.e-m-h.org/emh-history.pdf>. *See also* JUSTIN FOX, *THE MYTH OF THE RATIONAL MARKET: A HISTORY OF RISK, REWARD, AND DELUSION ON WALL STREET* (2009). Seminal articles, in the sense that they are generally accepted as presenting the first and most complete articulations of the efficient market hypothesis, are Eugene F. Fama, *Random Walks in Stock Prices*, 21 FINANCIAL ANALYSTS J. 55 (1965); Eugene F. Fama, *The Behavior of Stock-Market Prices*, 38 J. BUS. 34 (1965); and Paul A. Samuelson, *Proof That Properly Anticipated Prices Fluctuate Randomly*, 6 INDUSTRIAL MANAGEMENT REV. 41 (1965). *See also* Eugene F. Fama, *Efficient Capital Markets: A Review of Theory and Empirical Work*, 25 J. FIN. 383 (1970) (defining different forms of the efficient market hypothesis).

for risk management and trading strategies. Most importantly perhaps, an assumption of random future price movements has permitted the modeling of such movements on the basis of normal probability distributions, which has become the foundation for risk management strategies using derivative financial instruments.

Indeed, it is the development of a broad range of sophisticated derivative financial instruments, along with the provision of increased depth and liquidity of markets, which is routinely heralded as the principal efficiency-enhancing product of financial innovation undertaken during the prolonged period of prosperity from the mid 1980s to the present. The current financial landscape is thus characterized by an increasingly expanded range of positions – both long and short – in markets for the underlying assets on which derivatives are written.<sup>47</sup> The apparent result is a significant transformation of the relatively simplistic description of the debt-financing function articulated by Minsky. Yet the difference in the financial landscape is fundamentally one of degree and not one of kind.<sup>48</sup> As a source of instability, Minsky emphasizes the role of debt financing of capital assets. Derivative financial instruments simply provide an enhanced ability to place bets on price movements and to replicate leveraged positions in assets. By allowing investors to transact in asset markets at low cost, they have provided an ability to shed risk by transferring it to parties, who are assumed to be better able to

---

<sup>47</sup> See Stewart Mayhew, *The Impact of Derivatives on Cash Markets: What Have We Learned?* (Terry College of Business, University of Georgia, February 3, 2000), available at [http://www.terry.uga.edu/finance/research/working\\_papers/papers/impact.pdf](http://www.terry.uga.edu/finance/research/working_papers/papers/impact.pdf) (surveying the empirical literature and concluding that the evidence suggests that derivatives have either had no effect on volatility in underlying markets or have reduced volatility and have tended to improve the liquidity of these markets as well as the quality of information).

<sup>48</sup> In his account of financial crises from the mid-1960s to the mid-1980s, Minsky notes a range of innovations that permitted the banking sector, in particular, to avoid reserve requirements. See MINSKY, STABILIZING, *supra* note 9, at 15-106; and Hyman P. Minsky, *Securitization* (The Levy Economics Institute, Policy Note, 2008/2) (describing the causes and effects of securitization as an “originate and distribute” approach to the banking function). See also Viral V. Acharya & Matthew Richardson, *Causes of the Financial Crisis*, 21 CRITICAL REV. 195 (2009) (emphasizing the use of securitization by banks to avoid capital adequacy requirements).

bear it, as well as take on greater risk by scaling up bets on future price movements.<sup>49</sup> But in much the same way as the debt financing of capital assets, the resulting leverage effect – especially in the latter instance - is an additional source of financial instability for the same reasons identified by Minsky.

Moreover, instability associated with excessive risk taking and leverage using derivative financial instruments may be compounded by the mismeasurement of risk.<sup>50</sup> Despite an apparent ill fit with the data,<sup>51</sup> the integrity of the risk transfer market remains bound up in the efficient market hypothesis and its assumption of random price movements;<sup>52</sup> although it is now increasingly recognized that this assumption is incorrect, and risk-management models that are slavishly based on it systematically understate risk, contributing further to instability.<sup>53</sup> In other

See also Charles J. Whalen, *The U.S. Credit Crunch of 2007: A Minsky Moment* (The Levy Economics Institute, Public Policy Brief No. 92, 2007), at 12-13.

<sup>50</sup> See e.g., Stefan Thurner, J. Dooyne Farmer, & John Geanakoplos, *Leverage Causes Fat Tails and Clustered Volatility*, available at <http://www.arxiv.org/abs/0908.1555> (constructing a model of leveraged asset purchases with margin calls to demonstrate that leverage causes price fluctuations to become heavy tailed, displaying the clustered volatility characteristic of price fluctuations observed in real markets).

<sup>51</sup> The mathematician, Benoit Mandelbrot, developed fractal geometry to describe various natural phenomena, as well as price movements in markets for financial assets and commodities. See BENOIT MANDELBROT & RICHARD L. HUDSON, *THE (MIS)BEHAVIOR OF MARKETS: A FRACTAL VIEW OF FINANCIAL TURBULENCE* (2004) [hereinafter MANDELBROT, *MISBEHAVIOR OF MARKETS*]. See also BENOIT B. MANDELBROT, *FRACTALS AND SCALING IN FINANCE: DISCONTINUITY, CONCENTRATION, RISK* (1997).

<sup>52</sup> But see Burton G. Malkiel, *The Efficient Market Hypothesis and Its Critics* (CEPS Working Paper No. 91, April 2003), available at <http://www.princeton.edu/~ceps/workingpapers/91malkiel.pdf> (reviewing the challenges to the efficient market hypothesis in the academic literature and concluding that stock markets are more efficient and less predictable than these challenges suggest).

<sup>53</sup> MANDELBROT, *MISBEHAVIOR OF MARKETS*, *supra* note 51, at 79-107 (contrasting the wild randomness of financial markets with the mild randomness permitted by the efficient market hypothesis). The same general point is made by NASSIM NICHOLAS TALEB, *FOOLED BY RANDOMNESS: THE HIDDEN ROLE OF CHANCE IN LIFE AND IN THE MARKETS* (2d ed., 2004); and NASSIM

words, risk may be mismeasured because markets for financial assets differ fundamentally from markets for consumer goods and services. In particular, price movements in the market for financial assets are affected by the past in the sense that they tend to exhibit positive feedback effects;<sup>54</sup> it is characterized by a kind of memory and the associated clustering of sharp price movements. The positive feedback effects mean that standard probability distributions tend to understate extremes of price movements - both positively and negatively - which can only be captured in nonstandard distributions characterized by “fat tails” and “double peaks.”<sup>55</sup>

NICHOLAS TALEB, *THE BLACK SWAN: THE IMPACT OF THE HIGHLY IMPROBABLE* (1<sup>st</sup> ed., 2007). *See also* BOOKSTABER, *supra* note 43, at 143-64 (characterizing the derivatives market as a complex and tightly coupled network, attributable to the combination of liquidity and leverage, and thereby subject to crises when all contingencies cannot be anticipated); COOPER, *supra* note 25, at 151-52 (observing that the risk-management industry may inadvertently encourage excessive risk taking by producing probability distributions that are too narrow); Lux et al., *supra* note 4, at 4-7 (labelling as “control illusion” the false confidence provided by mathematical risk-management models based on an assumption of a normal probability distribution of asset price changes); and Thurner et al., *supra* note 50, at 4-6 (arguing that sophisticated risk-management techniques exacerbate extreme price fluctuations).

<sup>54</sup> *See e.g.*, Andrei Shleifer & Lawrence Summers, *The Noise Trader Approach to Finance*, 4 J. ECON. PERSP. 19 (1990) (arguing that investor demand for risky assets is affected by beliefs and sentiments which are not justified by fundamental news and that changes in such sentiments are not fully countered by the arbitrage trading of rational investors).

<sup>55</sup> *See e.g.*, Jon Danielsson, *Blame the Models*, 4 J. FINANCIAL STABILITY 321 (2008) (concluding that statistical models are useful for measuring the risk of frequent small events but not systemically important events). *See also* FINANCIAL SERVICES AUTHORITY, *THE TURNER REVIEW: A REGULATORY RESPONSE TO THE GLOBAL BANKING CRISIS* 39-49 (March 2009) available at <http://www.fsa.gov.uk/Pages/Library/Corporate/turner/index.shtml> [hereinafter THE TURNER REVIEW] (emphasizing the significance for capital adequacy requirements of the understatement of tail risk); Andrew G. Haldane, *Why Banks Failed the Stress Test* (Marcus-Evans Conference on Stress-Testing, February 9-10, 2009), available at <http://www.bankofengland/publications/speeches/.../speech374.pdf> (identifying disaster myopia, network externalities, and misaligned incentives as the sources of market failure that can cause mismeasurement of market risk); and Rene M. Stulz, *Risk Management Failures: What Are They and When Do They Happen?* (Fisher College of Business, Working Paper 2008-18, October 2008) [hereinafter Stulz, *Risk Management Failures*], available at <http://ssrn.com/abstract=1278073> (providing a taxonomy of risk management failures, including the mismeasurement of known risks which can be the result of: (i) the use of an incorrect probability distribution; (ii) mismeasurement of the correlation of returns across positions; or (iii) mistakes in information collection).

In sum, the source of financial instability emphasized by Minsky – excessive leverage – is substantially magnified by the introduction of a broad range of derivative financial instruments as both risk-creation and risk-transfer contracts in an environment characterized by mismeasurement of asset price risk.<sup>56</sup> In fact, Minsky’s two theorems, which focus on the debt-financed acquisition of capital assets, can be seen to apply analogously to transactions in derivatives. As already noted, the development of a broad range of derivative financial instruments has completed markets by providing economic units with desired payoffs for a broad range of contingencies that were previously unavailable. Hedge finance units can use this expanded range of positions to reduce their risk in risk-transfer transactions that are equivalent to insurance. Speculative and Ponzi finance units can use the same instruments, however, to place larger bets on price movements.<sup>57</sup> Proprietary trading desks and some hedge funds, for example, use sophisticated modeling techniques to identify price anomalies and the associated arbitrage opportunities, which are seized by taking positions often using substantial amounts of leverage.<sup>58</sup> But where price anomalies persist because of positive feedback effects, trading models can be

---

<sup>56</sup> See e.g., Nassim Nicholas Taleb, *The Fourth Quadrant: A Map of the Limit of Statistics*, available at [www.edge.rog/3rd\\_culture/taleb08/taleb08\\_index.html](http://www.edge.rog/3rd_culture/taleb08/taleb08_index.html) (concluding that an analysis of the power coefficient on data for a range of financial instruments indicates a value of between 2 and 3, with a mean absolute error greater than 1, which has devastating consequences for predictive value).

<sup>57</sup> See Stulz, *Risk Management Failures*, *supra* note 55, at 14 (emphasizing the need to make capital available to cope with unknown risks that, if known and captured in the relevant models, would alter the behavior of managers).

<sup>58</sup> Because this form of arbitrage trading provides likely small gains and a small chance of large losses, it has been described as the equivalent of “picking up nickels in front of a bulldozer.” See ROGER LOWENSTEIN, *WHEN GENIUS FAILED: THE RISE AND FALL OF LONG-TERM CAPITAL MANAGEMENT* 102 (2000). The phrase actually refers to “risk arbitrage” transactions, which are pure bets on the price movements of the shares of corporations that are expected to merge. This particular strategy differs significantly from convergence trades, relative value trades, and volatility trades, which are hedged trading strategies based on the identification of pricing anomalies.

subject to tracking error, and mark-to-market losses may be incurred in ever increasing size.<sup>59</sup> The accrued losses trigger margin calls that must be met by unwinding positions, which places further downward pressure on prices in markets that are often lacking depth. The resulting liquidity crisis can precipitate default for speculative and Ponzi finance units employing arbitrage-trading strategies or otherwise taking unhedged positions that are tantamount to “naked” bets on price movements.<sup>60</sup> As a specific example of this dynamic, the recent credit crisis differs from other financial crises only in the nature of the risk that was transacted and mispriced. Rather than asset price risk, credit risk was the focus of the innovative “originate and distribute” model of banking used to extend mortgage financing to Ponzi-finance households. The stripping of this risk and its transfer through credit default swaps was priced, however, using models that severely underestimated it.<sup>61</sup>

---

<sup>59</sup> See Andrei Shleifer & Robert W. Vishny, *The Limits of Arbitrage*, 52 J. FIN. 35 (1997) (arguing that arbitrage trading, as conducted by a small number of specialized investors, requires capital and entails risk, which has implications for security prices, including the possibility that arbitrage becomes ineffective when prices diverge far from fundamental values); and Shleifer & Summers, *supra* note 54, at 20-23 (emphasizing the limited and risky nature of arbitrage trading in an environment dominated by changes in price as a function of changes in sentiments and beliefs). See also Dilip Abreu & Markus K. Brunnermeier, *Bubbles and Crashes*, 71 ECONOMETRICA 173 (2003) (presenting a model in which asset bubbles persist despite the presence of rational arbitrageurs who are unable to coordinate selling strategies). *But see* Jefferson Duarte, Francis Longstaff, & Fan Yu, *Risk and Return in Fixed Income Arbitrage: Nickels in Front of a Steamroller?* 20 REV. FIN. STUDIES 769 (2005) (concluding that fixed-income arbitrage strategies tend to yield positively-skewed supernormal returns).

<sup>60</sup> The most notable case study of this dynamic is the rise and fall of Long-Term Capital Management. See LOWENSTEIN, *supra* note 58. See also NICHOLAS DUNBAR, *INVENTING MONEY: THE STORY OF LONG-TERM CAPITAL MANAGEMENT AND THE LEGENDS BEHIND IT* (2000).

<sup>61</sup> See e.g., Jan Kregel, *Minsky's Cushions of Safety: Systemic Risk and the Crisis in the U.S. Subprime Mortgage Market* (The Levy Economics Institute, Public Policy Brief No. 93, 2008) (emphasizing that the recent credit crisis was the result of insufficient margins of safety caused by the mispricing of risk in the US subprime mortgage market); and Barry Eichengreen, *Origins and Responses to the Crisis* (October 2008) at 6, available at [http://www.emlab.berkeley.edu/users/webfac/.../e183.../origins\\_responses.pdf](http://www.emlab.berkeley.edu/users/webfac/.../e183.../origins_responses.pdf) (noting that the credit risk models were based on a truncated and unrepresentative sample and were misspecified in their understatement of tail risk).

### C. MINSKY'S POLICY AGENDA

Because of the significance of financial relations and expectations of profits that underlie those relations, Minsky sees a sophisticated capitalist economy as inherently unstable; there is no equilibrium, but only phases of expanding or contracting credit.<sup>62</sup> There will be periods of tranquility when economic units are predominantly hedge finance units; but instability is latent as expectations of future profits become increasingly optimistic and economic units increasingly take on debt to finance increased investment. The key aspect of Minsky's financial instability hypothesis is, therefore, the notion that business cycles are the result of the internal workings of a capitalist economy and not external shocks.<sup>63</sup> Economies are not, as such, equilibrium seeking. Once they tip into a debt deflation, the process feeds on itself, and government must intervene to prop up aggregate demand and profits through deficit spending. Most importantly, the transfer payment system provides a floor for personal income, employment, and profits. The effect of a debt deflation on balance sheets can also cause the failure of one or more financial intermediaries, and central banks must serve as lenders of last resort for the banking system, providing loans and/or purchasing impaired assets<sup>64</sup> to prevent systemic failure attributable to the interlocking nature of relations among financial intermediaries. In discharging this function, central banks provide a floor for asset prices. As Minsky observes, government has to be

---

<sup>62</sup> The same feature is emphasized by Geanakoplos, *Leverage Cycle*, *supra* note 34, with the availability of credit determined by margin requirements.

<sup>63</sup> MINSKY, *STABILIZING*, *supra* note 9, at 172 (“...instability is determined by mechanisms within the systems, not outside it; our economy is not unstable because it is shocked by oil, wars or monetary surprises, but because of its nature.”). “Real business cycle theory” emphasizes external shocks, such as technology changes, as causes of the business cycle. *See e.g.*, N. GREGORY MANKIW, *MACROECONOMICS* ch. 19 (5<sup>th</sup> ed., 2003).

<sup>64</sup> *But see* John Geanakoplos, *Solving the Present Crisis and Managing the Leverage Cycle*, at 1-6 and 11-20 [hereinafter Geanakoplos, *Solving the Present Crisis*], available at <http://www.cowles.econ.yale.edu/~gean/crisis/solving-present-crisis.pdf> (outlining a more ambitious response to the credit crisis, including initiatives intended to prop up housing prices).

sufficiently large to discharge both of these functions.<sup>65</sup> Instability remains, nonetheless, and is only moderated in its effects.<sup>66</sup> Regulatory regimes attempt to address the associated moral hazard problem, which has been brought to the forefront of the public policy debate by the recent credit crisis.<sup>67</sup>

In an attempt to moderate financial instability, Minsky articulates a policy agenda that is not limited to regulatory supervision,<sup>68</sup> although it is his emphasis on the central bank's lender of last resort function as the principal stabilizing instrument in financial markets that has been emphasized by various commentators and fleshed out in more detail.<sup>69</sup> Minsky also advocates an

<sup>69</sup> See e.g., COOPER, *supra* note 25, at 124-40 (arguing that credit creation running substantially ahead of economic growth signals the development of an asset price bubble which monetary authorities should control by contracting the supply of credit); and BARBERA, *supra* note 41, at 188-89 (emphasizing the need for monetary policy to moderate asset price bubbles and monitor the appetite for risk as reflected in the spread between long-term rates on risky assets and long-term rates on government treasury bills). See also Geanakoplos, *Leverage Cycle*, *supra* note 34, at 3-6 (emphasizing the need for monitoring of leverage and its limitation during periods of prosperity as a complement to government intervention to support profits and asset prices during a debt deflation); and L. Randall Wray, *Financial Markets Meltdown: What Can We Learn from Minsky?* (The Levy Economics Institute, Public Policy Brief, Highlights, No. 94A,

aggressive antitrust policy designed to limit the size of institutions in the financial sector such that no one institution will be seen as “too big to fail.” Government would also act as employer of last resort by providing public service employment. This role is in addition to the use of counter-cyclical fiscal policy to prop up aggregate demand when private investment slows. But in terms of informative detail, Minsky’s discussion of the tax system as a fiscal policy instrument can be ignored without any appreciable loss of important insights. Indeed, this aspect of Minsky’s policy agenda, which focuses primarily on the broad mix of taxes, is extremely general and somewhat conventional.

Not surprisingly, Minsky argues that the tax system should provide government with sufficient revenue to support aggregate demand and profits in the face of a debt deflation. To realize this goal, he advocates a combination of a broad-based sales tax, preferably on the value-added model, and a progressive-rate personal income tax.<sup>70</sup> He prefers that the corporate income tax be eliminated on the apparent assumption that it is shifted forward to consumers and is inflationary.<sup>71</sup> Otherwise, Minsky has very little to say regarding the second-order details of tax design. He observes that the deductibility of corporate interest expense provides an undesirable tax bias in favor of debt finance in the context of an otherwise unintegrated tax on equity income.<sup>72</sup> Without much in the way of supporting analysis, he prefers conduit treatment of corporate income to prevent use of the corporate form as a tax-avoidance vehicle.<sup>73</sup> With

Minsky, *Uncertainty and the Institutional Structure of Capitalist Economies* (The Levy Economics Institute, Working Paper No. 155, 1996) (recommending the replacement of the personal income tax with a progressive personal consumption tax and a value added tax in order to fund a move from transfer payments to full-employment policies).

<sup>71</sup> MINSKY, STABILIZING, *supra* note 9, at 341-42.

<sup>72</sup> *Id.* at 340.

<sup>73</sup> Minsky says nothing about the treatment of losses.

apparent administrative and compliance costs in mind, he suggests broad application of the real estate investment trust (“REIT”) approach whereby a corporation that has distributed a minimum amount of its income annually is exempt from the tax that otherwise applies to nonqualifying corporations.<sup>74</sup> Much more interestingly, he argues that “nonproduction expenses, such as advertising, marketing, and the pleasures of the executive suites,” should not be deductible for corporate income tax purposes.<sup>75</sup> In effect, these expenses are considered returns to capital and should be treated consistently with returns to equity. He also notes, somewhat cryptically and briefly in passing, that tax policymakers need “to consider the behavior modification aspects of tax policy and use the expected tax avoidance reaction to foster policy goals.”<sup>76</sup> In this respect, he follows the standard legal definition of tax avoidance as a modification of behavior that legally results in a decrease or elimination of a taxed activity. Tax evasion, which is illegal, is defined as the nonpayment of taxes while continuing to carry on a taxed activity.

As Parts IV and V attempt to illustrate, Minsky’s financial instability hypothesis can be seen to have broad policy relevance for the resolution of certain tax-base rule choices, which have conventionally been framed as technical tax-policy issues. In fact, that relevance goes much deeper than was recognized by Minsky. I suggest first, however, in the following Part III, that a greater depth of policy analysis can be realized by reframing many of these rule choices as the subject of a tax-expenditure analysis focused on the moderation of excessive leverage and risk taking as the sources of financial instability emphasized by Minsky.

---

<sup>74</sup> Minsky is unclear whether the corporate income tax should be integrated with the shareholder-level tax, although he seems to cryptically suggest as much following his brief discussion of the REIT model. *See* MINSKY, *STABILIZING*, *supra* note 9, at 342 (“Either way, a unified income tax should be the major pillar of the tax system.”).

### III. TAX EXPENDITURES, TAX-EXPENDITURE ANALYSIS, AND CORRECTIVE TAXES

The literature on tax expenditures - both generally and in terms of analyses of particular programs - is deep and rich. No attempt is made here to come to grips with that literature.<sup>77</sup> Instead, this Part does nothing more than emphasize a general point that is more thoroughly developed by Neil Brooks.<sup>78</sup> That is, a substantial slice of the tax-expenditure literature - especially the literature in the United States - has undermined the significance of the tax-expenditure concept by unnecessarily focusing on the need to classify particular rules in tax legislation as either technical tax rules or tax expenditures. Contentiousness over the execution of this exercise has undercut the two important functions of the tax-expenditure concept: (i) the budgetary accounting function; and (ii) the policy analysis function. In this respect, it is suggested below in Part III.B that the manner in which the policy case in support of a particular provision is framed goes a long way in executing the necessary classification exercise for a broad range of provisions without any contentiousness.<sup>79</sup> For a minority of provisions, alternative modes of framing will be plausible and a tax-expenditure classification can defensibly be made for budgetary accounting purposes. Moreover, the full policy analyst's toolkit, encompassing both technical and budgetary criteria, can still be usefully applied.

---

<sup>77</sup> For a comprehensive review of much of this literature, see J. Clifton Fleming, Jr. & Robert Peroni, *Reinvigorating Tax Expenditure Analysis and Its International Dimension*, 27 VA. TAX REV. 437 (2008).

<sup>78</sup> Neil Brooks, *The Under-Appreciated Implications of the Tax Expenditure Concept*, in AUSTRALIAN BUSINESS TAX REFORM IN RETROSPECT AND PROSPECT 233, 234-37 (Chris Evans & Richard Krever eds., 2009) [hereinafter Brooks, *Under-Appreciated Implications*]. See also Edward D. Kleinbard, *How Tax Expenditures Distort Our Budget and Our Political Processes*, 123 TAX NOTES 925 (2009) [hereinafter Kleinbard, *How Tax Expenditures*].

<sup>79</sup> See e.g., Kleinbard, *How Tax Expenditures*, *supra* note 78, at 927 (“Tax expenditure analysis is a pragmatic exercise, and the existence of a handful of close questions should not obscure the fact that literally hundreds of other cases can be labelled as tax expenditures without much controversy.”).

At a more specific level relevant to the subject of this article, tax-expenditure analysis provides a conceptual framework that suggests directions in which Minsky's financial instability hypothesis might push the analysis of some important tax-base rule choices. As a tool of policy analysis, tax-expenditure analysis may be invoked by a change in emphasis on the consequential attributes of these rule choices attributable to the recognition of the potential significance of his financial instability hypothesis.

#### A. EXECUTING THE CLASSIFICATION EXERCISE BY SPECIFYING A BENCHMARK INCOME TAX

The tax-expenditure concept is deceptively simple. It requires the division of all rules in a tax system into two categories: technical tax rules and tax-expenditure provisions. The first set of rules defines the tax base, unit, period, and rate structure. The specific rules in each of these areas form the technical structure of the system designed to raise revenue. Tax-expenditure provisions are spending programs delivered through the tax system in the form of exceptions to that structure; they are designed to realize certain economic or social policies otherwise associated with comparable spending programs using alternative delivery mechanisms.

Although politicians and policymakers have long recognized that governments spend through the tax system,<sup>80</sup> the tax-expenditure concept was not developed in detail until the 1960s and early 1970s by Stanley Surrey,<sup>81</sup> who popularized the concept, coined the phrase, and wrote two definitive works on the subject.<sup>82</sup> According to Surrey, much of the debate about specific tax

---

<sup>80</sup> See e.g., Neil Brooks, *Current Tax Reading – Review of Stanley S. Surrey and Paul R. McDaniel, TAX EXPENDITURES*, 34 CAN. TAX J. 681, 683 (1986) (citing William Gladstone's Parliamentary critique of an income tax exemption for charities as spending through the tax system).

<sup>81</sup> But see Harry A. Shannon III, *The Tax Expenditure Concept in the United States and Germany: A Comparison*, 33 TAX NOTES 201, 203-04 (1986) (describing the development of the tax-expenditure concept in Germany in the 1950s).

<sup>82</sup> STANLEY S. SURREY & PAUL R. MCDANIEL, *TAX EXPENDITURES* (1985); and STANLEY S. SURREY, *PATHWAYS TO TAX REFORM: THE CONCEPT OF TAX EXPENDITURES* (1973).

provisions and their reform is really an issue of spending reform. The tax-expenditure concept allows the debate to be joined in terms of budgetary criteria relevant to such reform. From the outset of its development, however, the tax-expenditure concept has been contentious. Proponents have argued that the concept helps to clarify the size of government spending while also providing an analytical tool to assess the desirability of particular rules formally embedded in tax legislation. Critics have emphasized the problematic nature of a perceived need to identify a benchmark tax system as a premise for characterization of deviations as equivalent to spending programs.

The genesis of this definitional debate is undoubtedly the related critiques of the comprehensive tax base and the tax-expenditure concept articulated by Boris Bittker at the outset of the development of both.<sup>83</sup> Beginning with Bittker, critics of the tax-expenditure concept have argued that the Haig-Simons concept of income,<sup>84</sup> which the comprehensive tax base is seen to operationalize, is too difficult to translate into a workable norm. Furthermore, it says nothing about certain issues, such as the appropriate tax unit. In response, some proponents of the tax-expenditure concept have rejected the Haig-Simons concept of income in favor of a benchmark tax structure expressed in terms of what is “widely accepted by tax analysts.”<sup>85</sup> Others have

<sup>84</sup> HENRY C. SIMONS, *PERSONAL INCOME TAXATION*, 50 (1938) (defining income as the sum of present consumption and future consumption which is represented by changes in wealth); and R. Murray Haig, *The Concept of Income: Economic and Legal Aspects*, in *THE FEDERAL INCOME TAX* (R. Murray Haig ed., 1921).

<sup>85</sup> See e.g., SURREY & MCDANIEL, *supra* note 82, at 186-88. See also Dirk-Jan Kraan, *Off Budget and Tax Expenditures*, 4 OECD J. BUDGETING 121 (2004) (indicating OECD support of a benchmark based on current practice rather than a theoretical ideal).

vigorously defended the Haig-Simons concept of income as the basis for characterizing particular rules as tax expenditures, thereby triggering an accounting and analysis as spending programs.<sup>86</sup>

The lingering effects of the conceptual noise created by this perceived need to identify the elements of a benchmark tax system are evident in a recent report on tax expenditures prepared by the Staff of the US Joint Committee on Taxation.<sup>87</sup> In an attempt to avoid the characterization problems of the past, the Joint Committee report introduces what is described as “a new paradigm for classifying tax provisions as tax expenditures.”<sup>88</sup> In particular, the report proposes use of the existing provisions of US income tax law as the reference point for classification purposes, which is supposed to avoid contentiousness surrounding the articulation of a theoretically pure benchmark. The report proposes that tax provisions be characterized as tax expenditures if they can be considered either:

- deliberately inconsistent with an identifiable general rule of the present tax law (referred to as “tax subsidies”); or
- a structural element of the Internal Revenue Code that “materially affect[s] economic decisions in a manner that imposes substantial efficiency costs” (referred to as “tax-induced structural distortions”).<sup>89</sup>

<sup>88</sup> *Id.* at 1.

<sup>89</sup> See also Daniel N. Shaviro, *Rethinking Tax Expenditures and Fiscal Language*, 57 TAX L. REV. 187, 212, 228-30 (2004) [hereinafter Shaviro, *Rethinking Tax Expenditures*] (suggesting a separate category for structural rules which deviate from a theoretically pure income tax but differ from conventional tax expenditures “that seem more politically interchangeable with appropriations”). Much the same distinction has recently been proposed for reporting purposes in New Zealand. See Craig Fookes, *Spending through the Tax System: Tax Expenditures* (New Zealand Treasury Policy Perspectives Paper, 2009), available at <http://www.treasury.govt.nz/...>PolicyPerspectivesPapers>2009>.

After reviewing the historical development of tax-expenditure analysis in the United States, as well as the standard critiques of it, the Joint Committee report elaborates this proposed taxonomy in some detail, including a discussion of three subcategories of tax subsidies: (i) tax transfers; (ii) social spending; and (iii) business synthetic spending. The report emphasizes the use of the tax-expenditure concept as an analytical tool, with the proposed approach to characterization intended to allow tax-expenditure analysis to serve “as an effective and neutral analytical tool for policymakers in their consideration of individual proposals or larger tax reforms.”<sup>90</sup> This emphasis is much different than that in other countries where the tax-expenditure concept is used primarily as a weak budgetary accounting tool.<sup>91</sup> The Joint Committee report downplays this role, perhaps because of the apparent failure of the tax-expenditure account to control US federal government spending.<sup>92</sup> Yet, the tax-expenditure concept may well have its singularly independent policy significance in performing a budgetary accounting function, with characterization problems being much less problematic when the concept is limited to this role.

Perhaps more importantly - given the stated goal of the Joint Committee report to enhance the analytical function of the tax-expenditure concept - it is unclear whether the suggested characterization approach really does much to advance the whole tax-expenditure enterprise as a policymaking tool. In short, because the suggested categories are in no way self executing, it is not obvious that the proposed frame of reference solves what is assumed to be an

---

<sup>90</sup> JCT, RECONSIDERATION, *supra* note 87, at 1.

<sup>91</sup> See Shaviro, *Rethinking Tax Expenditures*, *supra* note 89, at 205 (observing that the intensity of the classification debate appears to be unique to the experience in the United States). The emphasis on a weak budgetary accounting function may be responsible, in part at least, for the much less contentious status of the tax-expenditure account in other countries.

<sup>92</sup> JCT, RECONSIDERATION, *supra* note 87, at 4 (noting that the first description of tax expenditures in 1972 consisted of 60 items, while 35 years later the description had expanded to 170 items using the same characterization approach).

insoluble problem.<sup>93</sup> In fact, the proposed taxonomy of tax expenditures appears to be based on the incorrect premise that characterization as a tax-expenditure provision accomplishes nothing unique for analytical purposes. An assumption of tax-policy agnosticism on this characterization issue is presumably advocated as a means to free policymakers to posit any set of rule choices, with the possibilities assessed on the basis of their efficiency and distributional effects, as well as administrative and compliance costs. Labeling a particular rule as a tax-expenditure provision apparently does nothing to advance this necessary policy analysis of the consequential attributes of possible rule choices.

It is more than just a bit ironic, however, that, as a means to enhance the analytical function, any difference in policy analysis triggered by a tax-expenditure characterization is deemphasized, which necessarily reduces the significance of the classification exercise. But technical tax-policy analysis and tax-expenditure analysis, albeit focused on the same consequential attributes, remain decidedly different because of a decidedly different emphasis on those attributes. It is this difference in emphasis that is central to the classification exercise when government discharges its allocative function using a particular policy instrument.<sup>94</sup> Adopting the taxonomy suggested in the Joint Committee report, a tax-induced structural distortion is only sensibly included as a tax expenditure if the associated behavioral response is intended by policymakers. Indeed, “deliberate inconsistency with an identifiable general rule of the present law” as indicative of a tax subsidy can only be determined if it can be concluded that the

---

<sup>93</sup> For example, the study cites tax relief for charitable donations as a supposedly clear example of a tax rule in its tax-subsidy category. It is not obvious, however, that tax relief, in the form of either a tax credit or an income deduction, for charitable donations can be considered deliberately inconsistent with an identifiable general rule of the present tax law. Similar characterization questions would appear to arise with the two examples of tax-induced structural distortions cited in the study: (i) deferral of foreign-source income earned through a foreign corporation; and (ii) the different treatment of corporate interest expense and dividends.

<sup>94</sup> See DANIEL N. SHAVIRO, TAXES, SPENDING, AND THE U.S. GOVERNMENT’S MARCH TOWARD BANKRUPTCY 174-93 (2007) [hereinafter SHAVIRO, TAXES, SPENDING]; and Shaviro, *Rethinking Tax Expenditures*, *supra* note 89, at 218-21.

behavioral response at issue is one that is intended by policymakers. The concept of a benchmark income tax base – however it may be conceived - is utterly irrelevant to this classification exercise.

#### B. EMPHASIZING BEHAVIORAL RESPONSE IN THE PRESENCE OF MARKET FAILURE

Brooks observes that there are two general problems with a perceived need to define a benchmark income tax system as the gateway to classification of particular rules as tax expenditures.<sup>95</sup> First, it is not clear what normative principles underlie such a system. Second, even if such a principle could be identified, operationalizing it involves balancing political and administrative considerations. These problems were similarly emphasized by Bittker and, as Brooks notes, they do not in any way undermine the usefulness of the tax-expenditure concept, which, as a form of conceptual reasoning, does not depend on “an empirical or normative judgment.”<sup>96</sup> Disputes about the precise dividing line between technical tax rules and tax-expenditure provisions do not mean, therefore, that the concept is incoherent and cannot serve its purpose of promoting clarity of thought;<sup>97</sup> yet this important point has been buried in the needless debate over a benchmark tax system and the execution of the characterization exercise as a trigger for the accounting and analytical functions associated with the tax-expenditure concept. Indeed, it is arguable that Bittker’s original point has been lost with the passage of time and the volume of subsequent literature on the tax-expenditure concept; or worse, it has been misstated in its significance.

Although well intentioned, traditional defenses of the tax-expenditure concept, grounded in the comprehensive tax base tradition, mistakenly tend to mask the significance of the

---

<sup>95</sup> Brooks, *Under-Appreciated Implications*, *supra* note 78, at 235. *See also* Kraan, *supra* note 85.

<sup>96</sup> Brooks, *Under-Appreciated Implications*, *supra* note 78, at 234.

<sup>97</sup> *Ibid.*

consequential attributes associated with various rule choices as the basis for a necessary distinction between technical tax rules and tax-expenditure provisions.<sup>98</sup> Although both technical tax-policy and tax-expenditure analyses involve consideration of the same consequential attributes, the emphasis is different, particularly where a tax-expenditure program is chosen by government in discharging its allocative function. As Shaviro suggests,<sup>99</sup> tax-rule choices that are seen as part of the technical architecture under an income tax tend to be made with a focus on the distributional aspects, while balancing them against administrative and compliance cost, as well as efficiency effects. These other consequential attributes are thus decidedly secondary in importance. In fact, many of the features of a Haig-Simons or comprehensive tax base are presumably preferred because of the perceived distributional effects. Revenue is ideally raised in a distributionally appealing manner at the lowest possible administrative and compliance cost, with tolerable efficiency costs attributable to behavioral response to the change in price occasioned by the particular tax rule. All else being equal perhaps, the rule that changes behavior least should be preferred because of its smaller deadweight loss. But as Bittker emphasized early on,<sup>100</sup> there are many rule choices that involve ambiguous distributional effects. In these instances, considerations of administration and compliance, along with tax politics and possible behavioral response, tend to move to the forefront of policy analysis.

Where a tax rule is chosen as an instrument to induce a behavioral response, the emphasis of the associated policy analysis obviously changes. Shaviro argues,<sup>101</sup> for example, that the government in this instance is discharging its allocative function, and distributional effects are decidedly secondary. This altered emphasis requires policymakers to invoke

---

<sup>98</sup> See e.g., Fleming & Peroni, *supra* note 77.

<sup>99</sup> SHAVIRO, TAXES, SPENDING, *supra* note 94, at 183-90; and Shaviro, *Rethinking Tax Expenditures*, *supra* note 89, at 207-13.

<sup>100</sup> Bittker, *Comprehensive Tax Base*, *supra* note 83.

<sup>101</sup> SHAVIRO, TAXES, SPENDING, *supra* note 94, at 183-91.

budgetary criteria in assessing the particular rule choice that is intended to induce the behavioral response. In effect, the analysis of the associated efficiency effects is no longer framed in terms of deadweight loss. A market failure requiring government spending in the form of the posited tax benefit must be identified,<sup>102</sup> and the welfare gain associated with the intended behavioral response should be estimated and weighed against the expected cost of providing the benefit measured as the sum of:

- administrative costs; and
- windfall gains attributable to the delivery of benefits to economic units who would engage in the desired behavior irrespective of the availability of any such benefits.

This quantitative targeting feature will be a function, in part at least, of the qualitative targeting aspects of the tax-rule choice. Over-inclusiveness will result in costs in the form of inframarginal gains. Under-inclusiveness will result in a range of economic units being excluded from the provision of benefits even though their behavior would be affected in the intended manner. In terms of rule choice, delivery of the program through the tax system should be compared with alternative policy instruments independent of the tax system,<sup>103</sup> since it is not a choice among alternative tax rules. Finally, the program itself – irrespective of the choice of delivery mechanism - should be assessed in terms of the government’s policy and spending priorities.

---

<sup>102</sup> An example of the analytical significance of different framing of the efficiency effects attributable to different tax treatments is the consumption tax treatment of savings for retirement, which may be justified as an instrument to correct certain cognitive biases that otherwise result in a suboptimal level of savings. *See e.g.*, AKERLOF & SHILLER, *supra* note 42, at 116-30. This framing, and the policy analysis that follows, is much different than that associated with the debate over the merits of the treatment of savings generally under a consumption versus an income tax, which centers on an assessment of the distributional and efficiency effects of the two possible treatments. Resolution of this timeless policy debate does not depend, in any way, on positing a market failure to be corrected by invoking a tax-based policy instrument. *See e.g.*, SHAVIRO, TAXES, SPENDING, *supra* note 94, at 181 (noting the objection of consumption tax advocates to the characterization of the consumption tax treatment of savings as a tax expenditure).

The characterization of a particular rule embedded in the income tax system as either a tax-expenditure provision or a technical tax rule can thus be seen as contingent on its rationale. This point was emphasized some time ago by McIntyre,<sup>104</sup> who argues that the tax system does not have to be unambiguously divided into technical tax rules and tax expenditures. If a particular rule is (or has been) justified as a spending provision, it should be analyzed as a spending program. As a means of conceptual reasoning, the tax-expenditure concept should be invoked whenever a rule embedded in the tax system is intended (or can be seen to be intended) to induce a particular behavioral response to correct a market failure, and government is thereby performing its allocative function. Where the classification of a particular rule might otherwise be contentious, McIntyre's classification paradigm errs on the side of a tax-expenditure characterization on the presumption that the provision of additional budgetary accounting information is useful, while enriching the policy analysis can only enhance discharge of the policymaking function. McIntyre's approach to the articulation of the tax-expenditure concept also embraces what are sometimes referred to as "negative tax expenditures"<sup>105</sup> as a class of rules that do not provide a tax benefit for particular behavior but impose an additional tax or tax penalty. Such provisions are commonly intended to correct a market failure by increasing the cost of the targeted behavior and are nothing more than Pigouvian corrective taxes; they should

---

<sup>103</sup> See David Weisbach & Jacob Nussim, *The Integration of Tax and Spending Programs*, 113 YALE L. J. 955 (2004) (emphasizing the relatively low delivery costs of tax-expenditure programs).

<sup>104</sup> Michael J. McIntyre, *A Solution to the Problem of Defining a Tax Expenditure*, 14 U. C. DAVIS L. REV. 79 (1980). McIntyre's argument was subsequently massaged by Victor Thuronyi, *Tax Expenditures: A Reassessment*, 1988 DUKE L. J. 1155 (1988) (proposing that a tax provision should be analyzed as a tax expenditure if it functions as a spending program). *But see* Brooks, *Under-Appreciated Implications*, *supra* note 78, at 235 (arguing that a functional approach identifies a majority of tax expenditures, but fails to do so in the case of some significant tax rules that are so over-inclusive they have no direct spending analogue).

<sup>105</sup> See *e.g.*, JCT, RECONSIDERATION, *supra* note 87, at 9 (labeling as a "negative tax subsidy" any provision that deliberately overtaxes as compared to the general rule).

be analyzed in the same manner as tax expenditures generally because they are intended (or can be seen to be intended) to induce a behavioral response.

By reconsidering the justification for some selected provisions that are commonly seen as technical tax rules, Parts IV and V illustrate the contingent nature of tax-expenditure classification and analysis emphasized by McIntyre. With moderation of excessive leverage and risk taking as the policy goal, it is suggested that some provisions can be framed as tax subsidies while others can be framed as corrective taxes. More particularly, tax-expenditure analysis moves the assessment away from a focus on consistency of tax treatment along the relevant behavioral margins to a focus on inconsistency as a means to bias behavior. Many provisions that are conventionally characterized as part of the technical tax structure can be characterized as tax expenditures intended to induce particular behavioral responses in the presence of market failure, with much the same result in terms of rule choice supported by familiar technical tax-policy arguments. These arguments are especially important, given that a tax-expenditure characterization of various rule choices highlights a significant targeting problem: that is, an inability to precisely calibrate the required amount of any tax subsidy or corrective tax. However, taxation clearly plays a secondary role to the use of regulatory instruments on the supply side of capital markets as a means to moderate excessive leverage and risk taking. This secondary role may mean that the quantitative targeting dimension is not as severe as it would be if a tax-based instrument were chosen as the principal instrument.<sup>106</sup> Moreover, much of the qualitative targeting dimension can be adequately executed. At a minimum, many of the practical considerations that have been seen to justify the particular tax-rule choices receive some enhancement from the application of tax-expenditure analysis.

---

<sup>106</sup> See e.g., Slemrod, *supra* note 5, at 389 (suggesting that some insight may be gained from applying the economics of Pigouvian taxes to systemic financial risk). *But see* Shackelford, Shaviro, & Slemrod, *supra* note 5, at 10-15 (emphasizing the difficulties in the design of Pigouvian taxes as a means to address systemic risk in the financial sector).

At the price of some confusion, therefore, the following two Parts slide back and forth between technical tax-policy analysis and tax-expenditure analysis in assessing tax-rule choices for the treatment of: (i) returns to corporate debt and equity; (ii) losses; and (iii) interest expense of individuals. It is hoped that this admittedly confusing mode of analysis illustrates the need for flexibility in the use of both sets of policy tools in areas where the line between technical tax rules and tax-expenditure provisions is somewhat blurred.

#### IV. DIVIDEND IMPUTATION SYSTEMS, CORPORATE CAPITAL STRUCTURE, AND MARGINS OF SAFETY

In the context of an explicit policy goal of moderation of financial instability, the tax-policy literature highlights a tax bias in favor of corporate debt, which is characteristic of most corporate income tax systems, as the most significant tax distortion requiring reform.<sup>107</sup> Moving from a conventional micro to a macro focus, this tax bias is seen to induce an excessive level of debt in the corporate sector generally, which leaves it vulnerable to economic downturns. A tax-rule choice that realizes complete consistency of treatment of returns to debt and equity finance would eliminate this instability-breeding bias. Depending on the particular parameters, a tax-rule choice that realizes something less than complete consistency of these same returns would mute, but not eliminate, the same bias. In an effort to realize complete consistency of tax treatment, the IMF paper, for example, advocates adoption of an allowance for corporate equity (“ACE”) system<sup>108</sup> as a preferred reform option; it is reluctant, however, to go further and recommend use of a tax penalty for debt finance, presumably because of the difficulty determining the appropriate level of such a penalty that would force firms to internalize the negative spillover effects associated with excessive leverage. By eliminating the tax bias for debt financing, it is

---

<sup>107</sup> See e.g., IMF PAPER, CRISIS-RELATED ISSUES, *supra* note 5, at 5-12. See also the other sources cited *supra* note 5.

<sup>108</sup> The ACE system was originally proposed in a study sponsored by the UK Institute for Fiscal Studies. See INSTITUTE FOR FISCAL STUDIES, EQUITY FOR COMPANIES: A CORPORATION TAX FOR THE 1990s (1991).

apparently assumed that a range of otherwise suboptimal investments will be forgone, with a reduction in the level of corporate leverage as an important secondary benefit. It is also apparently assumed that elimination of a tax bias in favor of corporate debt will induce a range of corporations to maintain stable hedge-finance states.

In advocating a strong form of consistent tax treatment, the IMF paper ignores some important policy constraints associated with the presence of tax-exempt and nonresident investors. These constraints mean that realization of consistent treatment for the entire range of investors is unrealistic, leaving a compromised application of dividend imputation systems as the preferred alternative to the double taxation of equity returns under classical corporate income tax systems. This compromised application manifests itself in two principal respects:

- maintenance of a debt tax bias for tax-exempt and nonresident investors; and
- provision of an equity tax bias for a range of taxable investors.

This Part suggests that the latter can be framed as a tax-expenditure program intended to promote maintenance of margins of safety. But this bias must be supported with a comprehensive deductibility limitation for corporate interest expense, which is the necessary tax penalty analogous to a corrective tax for debt finance under dividend imputation systems with incomplete consistency of taxation of debt and equity returns as a persistent feature in the presence of tax-exempt and nonresident investors.

#### A. INCONSISTENT TAXATION OF DEBT AND EQUITY RETURNS AND THE SIGNIFICANCE OF CORPORATE/INVESTOR RATE RELATIONSHIPS

Standard country practice permits the accrual-based deduction of corporate interest expense while requiring the inclusion of interest income by debtholders on the same basis. Dividends are non-deductible for issuers and are taxable to shareholders, with or without credit

for corporate tax paid on the underlying income.<sup>109</sup> Taking this different treatment as a given, the IMF paper provides a succinct review of the rate relationships that are the source of a tax bias in favor of debt for a range of investors. In fact, the parameters of these relationships are the subject of a deep corporate finance literature<sup>110</sup> on the theory of an optimal capital structure which lowers the after-tax cost of capital and maximizes shareholder wealth through the judicious use of debt. This literature begins with the work of Franco Modigliani and Merton Miller<sup>111</sup> (“MM”) and their fundamental insight stated in the form of the following proposition: In the absence of taxes, the value of a corporation is independent of its capital structure, and corporate debt policy is irrelevant. Their irrelevance proposition follows from two simple premises: first, that the value of a corporation is equal to the present value of the expected cash flows from its assets; and, second, that the relative mix of debt and equity securities divides those expected cash flows among investors. Accordingly, the sum of the present value of the expected cash flows associated with the outstanding debt and equity securities of a corporation must equal the present value of the expected cash flows associated with the underlying corporate assets. Critical to this proposition is a requirement of perfect capital markets (for example, the absence of information asymmetries) and a resultant insensitivity as between the investment policy of a corporation and its borrowing policy.<sup>112</sup> Under those conditions, the value of two corporations with the same asset

---

<sup>109</sup> An exemption for inter-corporate dividends ensures that there is only one level of corporate income tax on equity earnings.

<sup>110</sup> For accessible surveys of this literature, see Murray Z. Frank & Vidhan K. Goyal, *Trade-off and Pecking Order Theories of Debt*, in THE HANDBOOK OF EMPIRICAL CORPORATE FINANCE chap. 7 (Espen Eckbo ed., 2008); John R. Graham, *Taxes and Corporate Finance*, 16 REV. FINANCIAL STUDIES 1075 (2003); and Milton Harris & Artur Raviv, *The Theory of Capital Structure* 46 J. FIN. 297 (1991).

<sup>111</sup> Franco Modigliani & Merton H. Miller, *The Cost of Capital, Corporation Finance and the Theory of Investment*, 48 AM. ECON. REV. 261 (1958); and Franco Modigliani & Merton H. Miller, *Reply to Heins and Sprengle*, 59 (Part I) AM. ECON. REV. 592 (1969).

<sup>112</sup> There must also be no additional transaction costs associated with personal borrowing as a substitute for corporate borrowing.

profile must be equivalent, whatever their mix of debt and equity securities. This equivalence holds because any alteration of the risk and return mix realized by an alteration of the relative mix of corporate-level debt and equity can be replicated by investors through the substitution of investor-level debt for corporate-level debt. Investors will not pay a premium for shares of corporations with capital structures that have a mix of debt and equity, since any changes in the mix of corporate-level debt and equity securities are only changes in portfolio composition.<sup>113</sup>

As emphasized by MM, the introduction of taxes alters their analysis, primarily because of a tax bias in favor of corporate debt which can be used to lower the after-tax cost of capital.<sup>114</sup> In particular, the deductibility of interest expense permits the distribution of corporate income free of the corporate-level tax. Because of this shield from the corporate income tax provided by the interest expense deduction, corporate debt generates an increased after-tax return and lower cost of capital; in an important sense, the tax shield is an asset that adds value to a corporation and induces the issue of more debt than would otherwise occur in a world without taxes. An extensive literature<sup>115</sup> is important, however, for its emphasis on the more complex rate relationships that determine whether, in the aggregate, there is: (i) a tax bias in favor of debt or equity; and (ii) an optimal capital structure for particular corporations. In general, the focus of this literature is the expansion of the original MM analysis to account for the effect of investor-level taxes on debt and equity returns, as well as the impact of different effective corporate tax

---

<sup>113</sup> A necessary implication of the irrelevance of corporate debt policy is the notion that the expected return on the shares of a leveraged corporation increases in proportion to the debt-equity ratio. The increase in expected return occurs as an offset to the increase in risk borne by the shareholders of a leveraged corporation. Because the presence of corporate debt does not affect the expected operating income of the corporation or the total market value of its securities, the presence of borrowing does not affect the expected return on the underlying assets. All that is affected is the division of that return among investors.

<sup>114</sup> Merton H. Miller, *Debt and Taxes*, 32 J. FIN. 261(1977).

<sup>115</sup> See Joseph E. Stiglitz, *Taxation, Corporate Financial Policy and the Cost of Capital*, 2 J. PUB. ECON. 1 (1973). See also Graham, *supra* note 110, at 1077-1104 (surveying the extensive empirical literature on the relationship between taxes and corporate financial structure).

rates. To some extent, these additional factors operate to reduce and/or offset the present value of the tax shield from the corporate interest deduction, which reduces the tax bias in favor of debt. But even after accounting for differences in corporate and investor-level tax rates, there remains a general tax bias in favor of debt which arises largely because the investor-level tax on interest income is less than the two levels of tax on equity income for a range of investors.<sup>116</sup> The present value of the tax shield provided by the corporate interest deduction is sufficient, therefore, to induce corporations to issue more debt than they would in the absence of income taxes. The equilibrium point at which the present value of the tax shield equals the tax rate of the marginal investor is, in a general sense, drawn at a point that indicates a tax preference for corporate debt for a range of investors.

As explanations of this equilibrium, the trade off and agency theories of corporate capital structure posit that debt is issued to the point that direct and indirect costs of financial distress are equal to or less than the value of the associated tax shield.<sup>117</sup> In effect, the tax advantage associated with the deductibility of corporate interest expense induces a substitution of debt for equity to the point that the instruments are no longer perfect substitutes, and the substitution is considered inefficient because of the related nontax costs – both direct and indirect. Direct costs consist of the administrative and legal costs incurred in bankruptcy or a comparable legal proceeding that is invoked as the mechanism governing the orderly breakup or reorganization of an insolvent corporation.<sup>118</sup> Indirect costs consist of the more intangible costs associated with

---

<sup>116</sup> See e.g., Slemrod, *supra* note 5, at 388 (observing that the presence of tax-exempt investors means that an overall preference for corporate debt finance “almost certainly prevails”).

<sup>117</sup> See the sources cited *supra* note 110. But see also Roger H. Gordon, *Taxation and Corporate Use of Debt: Implications for Tax Policy*, 63 NAT’L. TAX J. 151 (2010) (reviewing the literature on capital structure theory and characterizing the market for corporate debt as presenting a classic lemons problem, which explains the under-use of corporate debt given the prevailing tax bias).

<sup>118</sup> The direct costs of financial distress attributable to bankruptcy proceedings are relatively easy to quantify; however, as most studies have concluded, such costs are relatively insignificant when measured as a percentage of asset value. The pioneering study of bankruptcy costs as a percentage of asset value is

difficulties encountered in the operation of a corporation as a going concern or in financial distress short of bankruptcy proceedings. These costs include the inefficiencies associated with asset substitution and underinvestment, which occur because of shareholders' decisions to pursue risky investments with zero or negative present values, as well as their decisions to forgo investments that would otherwise add value to a corporation.

In an attempt to prevent potential gaming by shareholders, creditors typically require restrictions and covenants limiting actions that might be detrimental to the value of the issued debt. Negotiation of these more complex contracts involves legal and administrative costs, along with monitoring costs incurred to ensure that the specified restrictions are observed. In this respect, Minsky's financial instability hypothesis posits that the necessary calibration of the nontax costs associated with debt financing fails during a period of prolonged prosperity, with a range of borrowers and their lenders overstating the adequacy of margins of safety as they move from hedge finance to speculative and/or Ponzi finance states.<sup>119</sup> With understatement of the associated nontax costs of debt finance, a tax bias for corporate interest expense is problematic as a further impetus to excessive risk taking.<sup>120</sup> Although it is now recognized that excessive leverage can be seen as a negative externality at a macro level,<sup>121</sup> the focus of the tax-policy

---

Jerold B. Warner, *Bankruptcy Costs: Some Evidence*, 32 J. FIN. 337 (1977) (examining eleven railroad bankruptcies in the United States and finding that, on average, the costs were only 5.3 percent of the value of all outstanding debt and equity of the corporations immediately before bankruptcy and only 1.4 percent five years before bankruptcy). *But see also* Edward I. Altman, *A Further Investigation of the Bankruptcy Cost Question*, 39 J. FIN. 1067 (1984) (finding that bankruptcy costs are not trivial).

<sup>119</sup> See e.g., Geanakoplos, *Solving the Present Crisis*, *supra* note 64, at 20 (observing that managers of borrowing funds do not typically fully internalize the costs of bankruptcy to society, including systemic risk attributable to falling asset prices in a debt deflationary environment).

<sup>120</sup> *But see* Michael S. Knoll, *Taxing Prometheus: How the Corporate Interest Deduction Discourages Innovation and Risk-Taking*, 38 VILL. L. REV. 1461 (1993) (arguing that the corporate interest deduction favors relatively safe projects involving the acquisition of tangible assets such as real estate and equipment, as well as mature corporations with established credit records).

<sup>121</sup> IMF, *CRISIS-RELATED ISSUES*, *supra* note 5, at 10. See also Slemrod, *supra* note 5, at 388 (noting the failure of public finance economists to account for spillover effects attributable to excessive leverage).

literature has been the firm-level distortion of investment that arises because of the negative cost of capital attributable to the combination of the corporate interest expense deduction and accelerated depreciation. In this tax environment, investments that are not profitable in the absence of taxes become profitable because of the tax system.

As noted above, the ACE system is preferred in the IMF paper as one particular approach that realizes consistency of treatment of the returns on corporate debt and equity and thereby equalizes the after-tax cost of both forms of capital. Under the ACE system, the corporate interest expense deduction is maintained, and a normal return is imputed on equity for deductibility purposes. This return, as well as interest income, is exempt for holders; any return in excess of the normal rate is subject to tax at both the corporate and shareholder levels. The ACE system is thus a non-distortive tax on economic rents, with consumption tax treatment of normal returns.<sup>122</sup> But as acknowledged in the IMF paper, there is only limited country experience with the ACE system,<sup>123</sup> which presents some difficult technical issues, including transitional problems and inconsistency with the much different premises of the international tax status quo.<sup>124</sup> Perhaps most importantly, the extension of interest imputation to equity capital for

---

<sup>122</sup> Edward Kleinbard's business enterprise income tax ("BEIT") also entails a deduction for an imputed cost of corporate capital - both equity and debt - equal to a normal rate, but with taxation at the investor level on an accrual basis. The BEIT is thus consistent with an income tax imposed on the normal rate of return to both debt and equity capital. Returns in excess of the normal rate would be taxed in a manner broadly similar to the ACE system. See EDWARD D. KLEINBARD, *REHABILITATING THE BUSINESS INCOME TAX* (2007); and Edward D. Kleinbard, *Designing an Income Tax on Capital*, in *TAXING CAPITAL INCOME* 165 (Henry J. Aaron, Leonard E. Burman, & C. Eugene Steurele eds., 2007).

<sup>123</sup> See Michael Keen & John King, *The Croatian Profits Tax: An ACE in Practice*, 23 *FISCAL STUDIES* 401 (2002); and Alexander Klemm, *Allowances for Corporate Equity in Practice*, 53 *CESIFO ECON. STUDIES* 229 (2007). See also IMF, *CRISIS-RELATED ISSUES*, *supra* note 5, at 14-15 (noting that adoption of an ACE system in Croatia may have reduced corporate income tax revenues by one-third, while the Fiscal Affairs Division of the IMF estimates that a revenue reduction of approximately one percentage point of gross domestic product has been experienced elsewhere).

<sup>124</sup> See e.g., John Isaac, *A Comment on the Viability of the Allowance for Corporate Equity*, 18 *FISCAL STUDIES* 303 (1997). There is no country experience with the BEIT system, which suffers from many of

deductibility purposes entails revenue loss, primarily because of the presence of tax-exempt and nonresident investors.<sup>125</sup> This revenue loss has tended to make the ACE system impractical in the presence of a budget constraint.

Denial of the corporate interest expense deduction is an obvious tax-reform alternative which attempts to realize consistency of treatment of returns to debt and equity while moderating revenue effects. This approach is developed most completely in the 1992 U.S. Treasury department study<sup>126</sup> proposing a comprehensive business income tax (“CBIT”). For various reasons, including its taxation of debt returns to tax exempts, the CBIT system is also problematic.<sup>127</sup> The Nordic dual income taxes (“DITs”), which are probably the closest operationalization of a CBIT system, attempt to manage some of these problems by maintaining

---

the same problems. See Alvin C. Warren, Jr., *The Business Enterprise Tax: A First Appraisal*, 118 TAX NOTES 921 (2008). *But see also* Edward D. Kleinbard, *BEIT Proponent Kleinbard Responds to Warren’s Critique*, 118 TAX NOTES 1043 (2008); and Daniel N. Shaviro, *Why the BEIT Shouldn’t Be Discounted*, 118 TAX NOTES 1048 (2008).

<sup>125</sup> See e.g., David A. Weisbach, *Reconsidering the Accrual of Interest Income*, 78 TAXES 36 (2000) (emphasizing the net revenue loss from a comprehensive accrual-based deduction/inclusion system in the presence of tax-exempt investors). New Zealand is the only OECD country without any form of consumption tax treatment for retirement savings. See Lisa Marriott, *Taxation of Retirement Savings: New Zealand – The Extreme Experiment*, 22 AUSTL. TAX F. 93 (2007).

<sup>126</sup> DEPT. OF THE TREASURY, INTEGRATION OF THE INDIVIDUAL AND CORPORATE INCOME TAX SYSTEMS: TAXING BUSINESS INCOME ONCE (1992). Interest and dividends would both be nondeductible at the corporate level and would be exempt from investor-level taxation. For a comparison of possible welfare effects under the ACE and CBIT systems, see Doina Maria Radulescu & Michael Stimmelmayer, *ACE versus CBIT: Which is Better for Investment and Welfare?* 53 CESIFO ECON. STUDIES 294 (2007). See also Ruud A. de Mooij & Michael P. Devereux, *Alternative Systems of Business Tax in Europe: An Applied Analysis of ACE and CBIT Reforms* (Taxation Papers, European Commission, 2009), available at [http://www.ec.europa.eu/taxation\\_customs/resources/documents/.../acecbit\\_study.pdf](http://www.ec.europa.eu/taxation_customs/resources/documents/.../acecbit_study.pdf).

<sup>127</sup> See also IMF, CRISIS-RELATED ISSUES, *supra* note 5, at 13-14 (noting the transitional difficulties presented by a CBIT system in dealing with pre-existing debt, as well as the possible denial of foreign tax credits and the need for a specialized regime for banks). Taxation of the same returns at higher rates to nonresidents means that the tax is unlikely to be creditable by those capital-exporting countries with foreign tax credit systems for foreign-source income. The move by the United Kingdom to an exemption system for business income from outbound direct investment leaves the United States and Japan as the major capital exporters operating foreign tax credit systems.

the corporate interest expense deduction and applying the corporate income tax on equity income either as a final tax (exemption at the shareholder level) or as a withholding tax (dividend imputation approach). In fact, as a particular expression of a CBIT system, the Nordic DITs have received considerable support in the tax-policy literature.<sup>128</sup> Much of their attractiveness lies, however, in the application of a single rate to all forms of capital income,<sup>129</sup> which permits the use of an interest withholding tax on deductible interest expense. The benefits of this single-rate structure are largely forgone where exceptions must be made for tax-exempt and nonresident investors, with a zero rate applied to their interest income returns and the single rate for capital income applied to equity returns through nonrefundability of dividend imputation credits. Where these features are maintained, much of the attractiveness of a DIT system is undermined, and it tends to converge with existing dividend imputation systems in its realization of an incomplete consistency of taxation of debt and equity returns.

It is suggested below in Part IV.B that this incomplete consistency of treatment of the returns to corporate debt and equity, which is characteristic of most dividend imputation systems, can be seen as a preferred tax-rule choice when policymakers move from the standard micro focus that has informed tax-policy analysis to a tax-expenditure perspective focused on excessive leverage at a macro level. In short, what is commonly viewed as a weakness of dividend imputation systems, but a necessary concession to revenue, administration, and compliance considerations, looks much different when viewed in this different policy light. It may even be appropriate to provide a preferential tax rate for share gains as a means to support a retention bias.

---

## B. INCOMPLETE CONSISTENCY UNDER DIVIDEND IMPUTATION SYSTEMS AND MAINTENANCE OF MARGINS OF SAFETY

Dividend imputation systems ideally ensure that only the shareholder-level tax is ultimately paid on distributed equity income, and the tax system is consistent in its treatment of the returns to debt and equity. This condition holds provided that the corporate income tax rate and the highest marginal personal income tax rate are equivalent, and shareholders receive full imputation credits for corporate tax on the underlying income from which dividends are paid. Under these strict parameters, a dividend imputation system ensures that the corporate income tax operates as a withholding tax on equity income, and there is no preference for debt or equity finance.<sup>130</sup> To varying degrees and for various reasons, however, national tax policymakers have failed to realize complete consistency of the returns to equity and debt for a range of investors. Although the policy pieces tend to be seen as the result of discrete technical tax-policy considerations, I suggest that the ostensibly incoherent whole can be rationalized as a tax-expenditure program intended promote maintenance of margins of safety in the corporate sector.

The IMF paper does not discuss dividend imputation systems in any detail, presumably because of certain structural features that combine to undermine consistency of treatment of debt and equity returns.<sup>131</sup> Three important features with this effect are:

---

<sup>130</sup> The “old view” of dividend taxation holds that the tax cost associated with dividend payments is traded off against nontax benefits, such as their signaling function and constraint on managerial discretion. In contrast with the “old view” of dividend taxation, the “new view” holds that, under specified conditions, the timing of dividend payments is irrelevant and there is no deferral benefit associated with retention of earnings. One of the specified conditions is, however, equivalence of corporate and personal income tax rates. Where the latter exceeds the former, there is a tax benefit to deferring dividend distributions. *See* Shaviro, *DECODING*, *supra* note 16, at 73-88 (reviewing the old and new view of dividend taxation, including the empirical literature attempting to determine which view has greater explanatory power). *See also* Graham, *supra* note 110, at 1104-11 (surveying the extensive empirical literature exploring the relationship between taxes and dividend payout policy).

<sup>131</sup> For a general description of dividend imputation systems in some selected countries, see HUGH J. AULT & BRIAN J. ARNOLD, *COMPARATIVE INCOME TAXATION* 405-09 (3d ed., 2010). Australia

- limitation of imputation credits to taxable resident shareholders of domestic corporations;
- provision of unfunded imputation credits computed as a function of statutory corporate income tax rates rather than effective rates; and
- adoption of a statutory corporate income tax rate that is lower than the highest marginal personal income tax rate.

For a range of taxable investors, each of these features lowers the tax rate on equity income and provides a preference for such investment over debt. Although this equity bias tends to be accepted by national tax policymakers as the tolerable outcome of structural compromises,<sup>132</sup> it may also be justified on tax-expenditure grounds. As an illustrative example of this kind of policy flexibility, limitation of the Canadian dividend tax credit (“DTC”) to resident individuals holding shares of “taxable Canadian corporations”<sup>133</sup> has sometimes been justified on technical tax-policy grounds and sometimes on the basis of two related subsidy rationales.<sup>134</sup> One subsidy rationale posits that the DTC is provided as a necessary stimulus for

---

and New Zealand operate full imputation systems whereby credit is provided only to the extent of corporate tax paid on the underlying income.

<sup>132</sup> See e.g., Fookes, *supra* note 89, at 18 (“Double taxation provisions would not be reported [that is, as tax expenditures] because they seek to align effective tax rates between different rate structures. For instance imputation credits align tax on investment income with personal tax rates. This is not motivated by any alternative policy goal.”).

<sup>133</sup> Income Tax Act, subsection 89(1), R.S.C., ch. 1 (1985) (5<sup>th</sup> Supp.) (Can.) [hereinafter ITA] defines a “taxable Canadian corporation” as a corporation that is incorporated in Canada and not statutorily exempt from income tax.

<sup>134</sup> See Tim Edgar, *Integration Canadian Style: Comments on the Dividend Tax Credit and the Recommendation of the Fair Tax Commission*, 9 TAX NOTES INT’L 1231 (1994) [hereinafter Edgar, *Integration Canadian Style*]. For a complete historical account of the DTC, see Neil Brooks, *Taxation of Closely-Held Corporations: The Partnership Option and the Lower Rate of Tax*, 3 AUSTL. TAX F. 381, 417-41 (1986) [hereinafter Brooks, *Taxation of Closely-Held Corporations*]. In the federal government’s 1979, 1980, and 1981 tax-expenditure accounts, the DTC was characterized and accounted for as a tax expenditure. In the 1985, 1992, and 1993 tax-expenditure accounts, this practice was changed, and the DTC was characterized as a partial integration mechanism, although its value as a tax expenditure was included as a memorandum item. Subsequent tax expenditure accounts are consistent with a characterization of the

investment in Canadian corporations. Proponents of this view apparently believe that, by reducing the burden of the double taxation of corporate income, the DTC should lead to increased equity investment in the Canadian corporate sector. This result is presumably achieved through an increase in the after-tax return on dividend income, which is assumed to translate into increased savings, a lower cost of capital, and increased growth.<sup>135</sup> A related subsidy rationale posits that the DTC is provided to encourage Canadian share ownership. This result presumably occurs because of the reduction in personal income tax provided by the DTC, which serves as an incentive for resident individuals to purchase shares of Canadian corporations, with assumed spillover benefits. Yet this very same feature of the DTC – limitation to resident individuals holding shares of taxable Canadian corporation – has also been justified as a technical design feature. In particular, the unavailability of the DTC for tax-exempts and nonresidents is sometimes supported on the basis of the prohibitive revenue cost of extending the credit on a refundable basis to these shareholders.<sup>136</sup> Similarly, provision of dividend imputation credits on an unfunded basis – that is, provision on an assumed amount of corporate tax paid as a function of the statutory rate – has also been justified on technical tax-policy grounds, such as

---

DTC as a technical tax provision. *But see* Robin Boadway, *The Annual Tax Expenditure Account – A Critique*, 55 CAN. TAX J. 106, 125 (suggesting that the DTC warrants classification as a tax expenditure because it does not accomplish the technical tax policy goal of avoidance of double taxation).

<sup>135</sup> The DTC was enhanced for resident individuals owning shares of publicly-traded Canadian corporations as a response intended to suppress demand for the income-trust structure and its associated debt-equity substitution. *See* DEPT. OF FINANCE, NEWS RELEASE 2005-082, (Nov. 23, 2005) (Can.). The proposal was implemented in legislation effective for dividends paid after 2005. Revenue cost apparently necessitated continued denial of the DTC for tax-exempts with the result that enhancement of the DTC did not suppress demand for the income-trust structure from this tax clientele. A subsequent legislative response was required to completely shut down the income-trust structure. *See* Tim Edgar, *Canadian Income Trust Saga: Over, or Headed for a Junk Bond Phase?* 45TAX NOTES INT'L 755 (2007). For a discussion of a system of full integration as a systemic response intended to eliminate the income trust market, see Lalit Aggarwal & Jack Mintz, *Income Trusts and Shareholder Taxation: Getting it Right*, 52 CAN. TAX J. 792 (2004); and Jack Mintz & Stephen R. Richardson, *Income Trusts and Business Investor Taxes: A Policy Analysis and Proposal*, 54 CAN. TAX J. 359 (2006).

<sup>136</sup> *See e.g.*, Mintz & Richardson, *supra* note 135, at 392-94 (estimating annual revenue loss of \$2.6 billion from the provision of a refundable DTC for tax-exempts in Canada).

administrative simplicity; or, alternatively, as a means of allowing the benefit of corporate losses and tax incentives to be passed on to shareholders as a tax subsidy, with the lower effective tax rate reflected in an assumed lower cost of equity capital.

Consistent with these other compromised features of dividend imputation systems, adoption of a statutory corporate tax rate that is lower than the highest marginal personal rate may also be rationalized as the outcome of technical tax-policy considerations or as a tax-expenditure provision. With respect to the former rationale, competition for mobile direct investment has placed considerable downward pressure on corporate tax rates. The result of this trend is that the statutory rate in many countries is lower than the shareholder-level tax rate for a range of investors. This rate gap provides the benefit of deferral through the retention of equity income at the corporate level.<sup>137</sup> As a function of tax competition, the gap is commonly seen as a technical design issue,<sup>138</sup> and - given an inability to stem pressure on the corporate tax rate - some reformers argue that it should be closed through a combination of base-broadening measures under the personal income tax and a lowering of the highest personal marginal rate.<sup>139</sup> But the rate gap can be framed, instead, in terms of a tax-expenditure rationale that is especially important for the promotion of maintenance of margins of safety. The Canadian experience is again instructive.

A lower statutory corporate tax rate has long been provided on a targeted basis for Canadian-controlled private corporations (“CCPCs”) on a specified maximum amount of annual

---

<sup>137</sup> See *supra* note 130.

<sup>138</sup> See George R. Zodrow, *Corporate Income Taxation in Canada*, 56 CAN. TAX J. 392 (2008).

<sup>139</sup> See *e.g.*, John G. Head & Richard Krever, *Australian Business Income Tax Reform in Retrospect: An Analytical Perspective*, in AUSTRALIAN BUSINESS TAX REFORM IN RETROSPECT AND PROSPECT 17 (Chris Evans & Richard Krever eds., 2009).

income from an active business carried on in Canada.<sup>140</sup> This lower rate of corporate tax, and the retention bias it entails where the shareholder tax rate is higher, has sometimes been justified as a technical tax-policy provision intended realize consistency of tax treatment between closely-held corporations and the unincorporated sector with which such corporations are seen to compete.<sup>141</sup> The same lower rate of corporate tax has also been justified, however, as a tax subsidy that is intended either:

- to correct for an equity capital market bias faced by closely-held corporations that are small to medium in size;<sup>142</sup> or
- to capture perceived spillover benefits associated with this sector.

Since it extends equally to the income of widely-held corporations and the income of closely-held corporations subject to the same general corporate rate, the retention bias that is the result of downward pressure on statutory corporate tax rates from international tax competition is obviously much broader in its effect. Any tax-expenditure rationale probably must change, therefore, from an attempt to correct for equity capital market biases, or to capture spillover benefits, to a perceived need to promote maintenance of margins of safety at the corporate level generally. In the context of closely-held corporations, a significant offsetting effect is a

---

<sup>140</sup> ITA, section 125. The specified maximum is currently \$500,000, with this amount shared by “associated” CCPCs. For a complete account of the history of this lower rate of corporate tax, see Brooks, *Taxation of Closely-Held Corporations*, *supra* note 134, at 437-50.

<sup>141</sup> See e.g., Boadway, *supra* note 134, at 126 (suggesting that the low rate of corporate tax for CCPCs may be characterized as part of the benchmark rate structure intended to ensure comparable treatment of incorporated and unincorporated small businesses).

<sup>142</sup> See Brooks, *Taxation of Closely-Held Corporations*, *supra* note 134, at 482-85; Claire Crawford & Judith Freedman, *Small Business Taxation* (Oxford University Centre for Business Taxation, Working Paper Series, WP08/06, April 2008), available at [http://www.sbs.ox.uk/tax/Documents/workinp\\_papers/WP0807.pdf](http://www.sbs.ox.uk/tax/Documents/workinp_papers/WP0807.pdf); and William McCarten, *Evaluating the Costs and Benefits of the Federal Small Business Deduction: A Framework for Tax Expenditure Evaluation* (Tax Policy Research Symposium sponsored by the Deloitte Centre for Tax Education and Research, University of Waterloo, July 2009). CCPCs with taxable capital employed in Canada in excess of \$15 million lose the benefit of the lower rate. See ITA, subsection 125(5.1).

distributional one, with higher-income individuals benefiting disproportionately from the deferral benefit associated with the lower rate. In the context of widely-held corporations, an offsetting effect is perceived agency costs arising in the form of managerial “cash burning.”<sup>143</sup> In other words, efficiency losses can result because earnings retention may be preferred for tax purposes even though, for nontax purposes, investors would be better off receiving the earnings in the form of dividends and reinvesting the after-tax amount in projects with greater expected returns.<sup>144</sup> The distributional effect can be addressed, in the worst instances at least, by imposing a refundable tax approximating the highest marginal personal rate on retained income that is not reinvested in an active business.<sup>145</sup> The agency cost effect may be addressed through corporate governance innovations - both regulatory and market based.<sup>146</sup> It is nonetheless unclear whether

---

<sup>143</sup> See e.g., Michael C. Jensen & William H. Meckling, *Theory of the Firm: Managerial Behavior, Agency Costs, and Ownership Structure*, 1976 J. FIN. ECON. 305 (1976).

<sup>144</sup> The apparent need to control agency costs attributable to corporate management’s control of excess cash flow is a specific application of the generalized argument for elimination of a perceived tax bias in favour of retention of earnings under a classical corporate income tax. In particular, the nontax significance of the signalling function served by dividend payments is the focus of a substantial literature on the desirability of consistency of tax treatment of distributed and retained earnings. For a review of some of this literature, see Kim Brooks, *Learning To Live with an Imperfect Tax: A Defence of the Corporate Tax* 36 UBC L. REV. 621, 659-63 (2003). Agency costs are emphasized in some of the literature as a political explanation for the durability of the double tax on equity income. See e.g., Jennifer Arlen & Deborah M. Weiss, *A Political Theory of Corporate Taxation*, 105 YALE L.J. 325 (1995). But see also Michael C. Doran, *Managers, Shareholders, and the Corporate Double Tax*, 81 VA. L. REV. 517 (2009) (emphasizing heterogeneity of interests of shareholders, corporate managers, and third parties in the debate over the desirability of corporate integration and different methods of integration).

<sup>145</sup> See the refundable dividend tax on hand (“RDTOH”) mechanism in ITA, section 129. Much the same problem arises under the Nordic DITs. The lower rate on capital income means that an imputed return on equity capital must be determined for small businesses, both incorporated and unincorporated, which combine the capital and labor inputs of the participants. In effect, the imputed return operates as an upper limit that attempts to limit the ability to disguise labor returns as capital income. The Canadian corporate tax system for closely-held corporations permits returns to labor to be taxed at the lower corporate rate equally with returns to financial capital up to the annual business limit for active business income.

<sup>146</sup> See e.g., Jensen & Meckling, *supra* note 143 (emphasizing the use of debt to reduce free cash flow otherwise available to managers where monitoring is costly and imperfect). See also Michael C. Jensen, *Eclipse of the Public Corporation*, 67 HARV. BUS. REV. 61 (1989) (defending the use of high-yield debt

these offsetting effects can be sufficiently muted to warrant provision of a retention bias as a means of promoting maintenance of margins of safety and a hedge finance state at the firm level. Because acceptance of a corporate/shareholder rate gap may be the more broadly effective tax-rule choice to realize this goal, these offsetting effects are especially significant.

By lowering the cost of equity capital and inducing the issue of new equity capital, the provision of dividend imputation credits for resident shareholders on an unfunded basis may also be rationalized as an attempt to promote maintenance of margins of safety rather than increased domestic ownership of the domestic corporate sector or increased output by that sector. Whatever the particular subsidy rationale, the desired effect may be substantially diluted where national capital markets are well integrated with international capital markets and are relatively small in the sense that the domestic savings rate has virtually no impact on world interest rates.<sup>147</sup> These conditions mean that the cost of finance for a range of domestic corporations is determined by international capital markets independent of the level of domestic savings. As a result, any increase in the level of domestic savings because of personal income tax reductions may simply result in a reduction in the level of foreign savings invested in domestic corporations or an increase in the level of domestic savings invested in foreign assets. The dominant effect of a limitation of dividend imputation credits to resident investors may thus be a portfolio shift by residents away from debt and into shares of domestic corporations, with nonresidents shifting away from shares of the same corporations. Any stabilizing effect at the corporate level would be realized at the cost of an offsetting assumption of additional risk by households, while providing

---

in leveraged buy outs in the 1980s). For a reprise of this argument in the context of the high-yield, subordinated junk debt used in income-trust structures in Canada, see Benjamin Alarie & Edward M. Iacobucci, *Tax Policy, Capital Structure, and Income Trusts*, 45 CAN. BUS. L.J. 1 (2007).

<sup>147</sup> See Robin Boadway & Neil Bruce, *Problems with Integrating Corporate and Personal Taxes in an Open Economy*, 48 J. PUB. ECON. 39 (1992); and GOV'T PROV. ONT., FAIR TAXATION IN A CHANGING WORLD: REPORT OF THE ONTARIO FAIR TAX COMMISSION 343 (1993) (Ont.) (recommending restructuring or repeal of the provincial portion of the DTC in the face of increasing integration of capital markets).

dubious spillover benefits associated with “national” share ownership.<sup>148</sup> These kinds of offsetting portfolio shifts would arguably occur most readily with large multinational corporations whose shares trade internationally. Viewed in the best possible subsidy light, therefore, limitation of dividend imputation credits to resident individuals may help to reduce equity capital market biases for small and medium-sized domestic corporations that are closely held. For those corporations, dividend imputation can actually result in an increase in the total amount of their equity capital<sup>149</sup> and, through a consequent reduction in their reliance on debt finance, an increase in their margins of safety.

In fact, the revenue imperative associated with the provision of refundable credits for tax-exempt and nonresident investors is probably the more compelling basis for the limitation of dividend imputation credits to taxable resident shareholders of domestic corporations. As an incidental effect, denial of imputation credits for tax exempts and nonresidents can mute demand for dividend distributions and reinforce a retention bias with its maintenance of margins of safety.<sup>150</sup> Ideally, a focus on reinforcement of this bias dictates adoption of an advance corporation tax (“ACT”) applicable to dividend distributions to ensure that imputation credits are available only to the extent of actual tax paid. At its most fundamental level, an ACT attempts to

---

<sup>148</sup> GLENN P. JENKINS, *THE ROLE AND ECONOMIC IMPLICATIONS OF THE CANADIAN DIVIDEND TAX CREDIT* (1986) (estimating that the suboptimal allocation of investment portfolios caused by the DTC imposes an annual economic cost of \$500 million).

<sup>149</sup> See Kenneth J. McKenzie, *Income Taxes, Integration, and Income Trusts*, 54 CAN. TAX J. 633 (2006) (surveying the mixed evidence for the open-economy model and suggesting that the capital market in Canada may be segmented such that the open-economy characterization applies to some investors and corporations while a closed-economy characterization applies to others).

<sup>150</sup> By segmenting shareholders, dividend streaming delivers the benefit of tax shielding of corporate income to those shareholders who value it most. Dividend streaming is a significant problem for dividend imputation systems and has required specific anti-avoidance legislation. See e.g., Mark P. Gergen, *How Corporate Integration Could Kill the Market for Corporate Tax Shelters*, 61 TAX L. REV. 145 (2008) (observing that the provision of full integration through, for example, refundable imputation credits causes different valuations of the benefit of tax shielding among shareholders subject to different tax rates and/or with different investment time horizons).

limit the benefit of corporate tax expenditures, as well as any mismeasurement of income through the use of financial accounting conventions, to retained earnings.<sup>151</sup> Washing out of the value of corporate tax preferences and income mismeasurement on distribution is usually based on the empirical premise that the delivery of corporate tax preferences is not sufficiently enhanced through a lower cost of capital associated with the flow through to shareholders. With correction of excessive risk taking through excessive leverage as the policy goal, the associated retention bias is the more important effect. But national tax policymakers must still determine that the administrative and compliance costs associated with an ACT are less than the benefits attributable to such a bias.<sup>152</sup>

Denial of imputation credits for tax-exempt and nonresident investors means, of course, that a tax bias in favor of corporate debt continues to hold for such investors. In the absence of a generalized rule of nondeductibility for corporate interest expense, this debt tax bias may be addressed by comprehensive thin capitalization or earnings stripping rules.<sup>153</sup> This particular

---

<sup>151</sup> Adoption of an ACT to wash out corporate level preferences on distribution of tax-preferred income may be especially important for the financial services sector in the event that general or dynamic loan loss provisioning is used for regulatory purposes and is accepted, rather than more restrictive specific provisioning, as an additional means of promoting maintenance of margins of safety. *See e.g.*, IMF, CRISIS-RELATED ISSUES, *supra* note 5, at 17 (noting that dynamic or general provisioning includes a systematic and mandatory counter-cyclical element but raises tax issues); and IMF, LESSONS, *supra* note 67, at 13-14 (reviewing various forms of prudential reserve provisioning).

<sup>152</sup> For a review of some of the relevant issues, see Edgar, *Integration Canadian Style*, *supra* note 134, at 1240-44. An especially contentious policy issue is the treatment of foreign-source income earned by domestic corporations. Application of a comprehensive ACT treats foreign-source income much like a tax expenditure and washes out any recognition of source-country tax on distribution as a dividend. *See e.g.*, C. John Taylor, *Alternative Treatments for Foreign Source Income in Australia's Dividend Imputation System*, 20 AUSTL. TAX F. 189 (2005) (discussing the effects of a range of alternative treatments of foreign-source income under a dividend imputation system that attempts to ensure that credit is limited to tax-paid corporate income). The administrative and compliance costs of an ACT regime are limited in Canada to preferred shares that can be considered tax-driven debt substitutes. *See* ITA, parts IV.1 and VI.1.

<sup>153</sup> *See e.g.*, Internal Revenue Code, 1986, section 163(j) [hereinafter "IRC"]. The "thin capitalization" label is used here to include earnings-stripping legislation, recognizing that the design features of the different

legislative response is noted only briefly in the IMF paper and is criticized as ad hoc in nature.<sup>154</sup> The characterization may be attributable to the fact that the rationale for and design details of existing regimes vary considerably. Even so, there are two emerging trends in such legislation which potentially give it some conceptual coherence.<sup>155</sup> One trend is a move away from a focus on the use of related-party debt as disguised equity in favor of an application to all debt – both related-party and arm’s-length debt – in an effort to limit the deductibility of corporate interest expense within a specified leverage ratio. Another trend is a move away from a focus on inbound direct investment to either:

- symmetrical application in the context of outbound and inbound direct investment; or
- application equally in a purely domestic context and a cross-border context (both inbound and outbound).

In the cross-border context, application of thin capitalization legislation to all debt of a corporation can be rationalized as an attempt to limit the tax-driven sourcing of the interest expense of multinational corporate groups in the context of both inbound and outbound direct investment. In the purely domestic context, similar application of thin capitalization legislation can be rationalized as an attempt to moderate the tax bias in favor of debt for a range of investors, including tax exempts and private-equity funds.<sup>156</sup>

---

legislative regimes differ in some important respects. For a comparison of these different features, see Tim Edgar, *The Thin Capitalization Rules: Role and Reform*, 40 CAN. TAX J. 1 (1992).

<sup>154</sup> IMF, CRISIS-RELATED ISSUES, *supra* note 5, at 13.

<sup>155</sup> Tim Edgar, Jonathan Farrar, & Amin Mawani, *Foreign Direct Investment, Thin Capitalization, and the Interest Expense Deduction: A Policy Analysis*, 56 CAN. TAX J. 803 (2008).

<sup>156</sup> The extension in some EU countries of interest deductibility restrictions to arm’s-length debt has been motivated by the European Court of Justice’s characterization of thin capitalization regimes that are limited to related-party debt in the context of inbound direct investment as a violation of the right to freedom of establishment under the EC Treaty. See Christoph Kaserer, *Restricting Interest Deductions in Corporate Tax Systems: Its Impact on Investment Decisions and Capital Markets* (European Private Equity and Venture Capital Association Special Paper, March 2008), at 5 (suggesting that the adoption of thin

Although the associated rationale differs depending on the context, the different rationales do not mean that thin capitalization legislation is ad hoc in nature. Indeed, a comprehensive application of thin capitalization legislation to limit the deduction of corporate interest expense within a specified leverage ratio can comprehensively constrain the scope of a tax bias in favor of debt finance and support maintenance of margins of safety at the firm level. A difficult targeting issue is the specification of an acceptable leverage ratio. Admittedly, there will be an element of arbitrariness in the choice of a specified ratio at the firm level, with particular industry mean or median ratios serving as rough benchmarks.<sup>157</sup> Moreover, with the possible exception of the financial sector - where regulatory capital ratios can be used for tax purposes - any correlation between a targeted macro limitation on credit creation as indicative of declining margins of safety and the results produced by aggregate leverage ratios at the firm level, as constrained by comprehensive thin capitalization legislation, will also be somewhat random.<sup>158</sup> In effect, specification of a permissible leverage ratio at the firm level can produce defensible results at a macro level, albeit entirely incidentally.<sup>159</sup> Because it is less sensitive to changes in asset value and earnings, thin capitalization legislation that is intended, at least in part, to

---

capitalization and earnings-stripping legislation applicable to arm's-length, as well as related-party debt, has been motivated by concern over income shifting by multinationals and the high leverage ratios resulting from corporate acquisitions by private-equity funds). *See also* Lloyd, *supra* note 5, at 19 (suggesting that country "best practice" standards be developed for the application of thin capitalization rules to leveraged buyout cases).

<sup>157</sup> Regulatory ratios provide a convenient benchmark for the financial services sector. *See e.g.*, ITA, section 20.2 (providing a 95 percent debt-to-risk-weighted-assets ratio for authorized foreign bank branches). The Australian thin capitalization legislation specifies the level of permissible debt for authorized deposit-taking institutions ("ADIs") in terms of a required capital base equal to 4 percent of risk-weighted assets. *See* Income Tax Assessment Act, 1997, Division 820 (Austl.) [hereinafter ITAA, 1997].

<sup>158</sup> *See* Geanakoplos, *Leverage Cycle*, *supra* note 34, at 5-6 (emphasizing the lack of data on leverage levels, which are defined as the "ratio of collateral values to the down payment that must be made to buy them").

<sup>159</sup> *See* IMF, CRISIS-RELATED ISSUES, *supra* note 5, at 11-12 (observing that the tax bias in favour of corporate debt may undercut the effectiveness of regulatory requirements for the financial services sector, with the impact of externalities at a macro level likely to be especially large for this sector because of its systemic importance).

moderate financial instability should probably be based on tax-book asset value. This approach allows the constraint on leverage levels for income tax purposes to operate somewhat independently of the market forces that can otherwise lead to increasing levels of leverage as a function of rising asset values and earnings.<sup>160</sup>

The incomplete consistency of taxation that is characteristic of dividend imputation systems also leaves in place the significance of the familiar tax-law boundary between debt and equity. By combining features commonly associated with one or the other form of instrument, debt-equity hybrids can be used in an attempt to:

- change the tax-law character of dividend payments to interest (“tax-deductible equity”); or
- change the tax-law character of interest payments to dividends (“debt-like shares”).

The conventional tax-policy focus is the revenue loss and efficiency effects associated with tax-driven substitution along this tax-law boundary.<sup>161</sup> However, as the IMF paper notes, the substitution of tax-deductible equity for debt may “ease the inefficiencies created by differential tax treatment of the two, although at the cost of loss of revenue ... and increased complexity and

---

<sup>160</sup> See Geanakoplos, *Leverage Cycle*, *supra* note 34, at 5-6. Permitted tax-leverage ratios could follow regulatory ratios generally for specified asset classes and could be set at lower levels during periods of prosperity in an effort to moderate the leverage cycle. Such an approach would be particularly important for traders or dealers who mark financial assets and liabilities to market for income tax purposes. See *infra*, note 209. “Dynamic provisioning” for portfolio losses varies regulatory capital requirements through the business cycle by building up a margin of safety for losses yet to be incurred during an economic upswing and allowing some losses to be met in a downswing from this margin of safety. See *e.g.*, THE TURNER REVIEW, *supra* note 55, at 61-67.

<sup>161</sup> The different income tax treatment of interest and dividends and the associated boundary between debt and equity have preoccupied tax policymakers, tax administrators, and tax practitioners while attracting considerable attention in the academic literature. There are two quite distinct types of this literature. One type focuses on fundamental reform intended to realize consistency of treatment of debt and equity. Another type focuses on execution of the tax-law boundary. For an interesting combination of these two types of literature, see Katherine Pratt, *The Debt-Equity Distinction in a Second-Best World*, 53 VAND. L. REV. 1055 (2000).

opacity of financial arrangements.”<sup>162</sup> In other words, tax-deductible instruments with equity features are imperfect substitutes that can enhance margins of safety, but at the cost of lost revenue and otherwise desirable nontax features.

The extent to which hybrid instruments are developed as tax-driven substitutes remains unclear empirically,<sup>163</sup> with various nontax factors appearing to constrain complete substitutability.<sup>164</sup> Furthermore, tax-law uncertainty acts as an additional friction that constrains tax-driven innovation of publicly-traded securities because of the pricing effect for tax clienteles.<sup>165</sup> In this environment, tax policymakers and tax administrators have tended to use a combination of specific anti-avoidance rules, classification rules targeted to particular hybrids, and a generalized factors approach to constrain taxpayer electivity along the debt-equity boundary.<sup>166</sup> Because comprehensive thin capitalization rules are premised on a prior characterization of particular instruments as debt or equity, they can address the use of such

---

<sup>162</sup> IMF, CRISIS-RELATED ISSUES, *supra* note 5, at 11.

<sup>163</sup> A notable exception is Ellen Engel, Merle Erickson, & Edward Maydew, *Debt-Equity Hybrid Securities*, 37 J. ACCN’G RES. 249 (1999) (examining a particular form of tax-deductible preferred shares, referred to as trust preferred stock (“TRUPs”), to identify: (i) the extent to which firms will incur costs to manage the balance-sheet classification of a security; (ii) the magnitude of the tax benefits associated with the additional leverage; and (iii) the extent of investor-level implicit taxes). *See also* Gordon Mackenzie, *Taxation as a Driver for Designing Hybrid Securities*, 1 J. APPL. RES. ACCOUNTING & FIN 31 (2006) (suggesting that the design of hybrid securities in Australia was driven more by accounting and regulatory changes than the adoption of comprehensive debt-equity classification rules for income tax purposes).

<sup>164</sup> *See e.g.*, Shaviro, *Financial Crisis*, *supra* note 5, at 5 (“If taxpayers can simply marry the preferred economic characteristics of financial arrangements to whichever tax label (debt or equity) they prefer – a situation that increasingly prevails although still not entirely – then the problem is simply one of making aggressive tax planning too easy ...”).

<sup>165</sup> *See* Mark P. Gergen & Paula Schmitz, *The Influence of Tax Law on Securities Innovation in the United States: 1981-1997*, 52 TAX L. REV. 119 (1997).

<sup>166</sup> Australia is notable in its adoption of legislation that purports to comprehensively classify all financial instruments as debt or equity based on the presence of noncontingent payments. *See* ITAA, 1997, Division 974.

instruments only indirectly. Nonetheless, by constraining the use of all forms of tax-deductible debt (whether hybrid in nature or not), a comprehensive thin capitalization regime is a direct and potentially effective policy instrument implicated by a focus on promotion of maintenance of margins of safety. Introduction of the same focus as a policy-relevant factor in the execution of the debt-equity classification exercise would not appear to add anything of definitive policy value, given the lack of empirical knowledge of the extent of the use of tax-deductible hybrids with equity features that might enhance maintenance of margins of safety.<sup>167</sup>

### C. TAXATION OF SHARE GAINS

At least as an initial proposition, there is nothing special about capital gains, as a subset of disposition gains, which would suggest that the concept be used as a gateway to the provision of a lower tax rate. Appreciation in the value of an asset over its cost is a gain, and any decline is a loss. These critical values are determined by discounting expected cash flows at an appropriate risk-adjusted rate. The passage of time reveals changes in expectations that affect those cash flows and, in turn, the value of the asset. The fact that cash flows are realized on disposition, producing a gain or a loss, is arguably an arbitrary basis for recognition at a reduced rate. Moreover, the fact that an asset is acquired for the purpose of trading does nothing to alter the nature of the associated cash flows in a manner that should alter the tax treatment. There is, however, an enormous literature challenging these simplistic propositions and articulating various reasons for preferential treatment of capital gains.<sup>168</sup> The narrow point made briefly here in Part IV.C is that, even where standard tax rates are applied to gain or loss on financial instruments generally, an exception to noncapital treatment might defensibly be made for share

---

<sup>167</sup> The same empirical uncertainty holds with the use of such hybrids to discipline managerial “cash burning.” *See supra* note 146.

<sup>168</sup> For a comprehensive review of these arguments, see RICK KREVER & NEIL BROOKS, *A CAPITAL GAINS TAX FOR NEW ZEALAND* 41-86 (1990). *See also* LEONARD E. BURMAN, *THE LABYRINTH OF CAPITAL GAINS TAX POLICY: A GUIDE FOR THE PERPLEXED* 42-83 (1999); and OECD, *TAXATION OF CAPITAL GAINS OF INDIVIDUALS: POLICY CONSIDERATIONS AND APPROACHES* (2006).

gains in an attempt to approximate the shareholder tax rate on dividends. Rather than the standard anti-avoidance rationale, this rate equivalence can be justified as an attempt to further reinforce a retention bias and the promotion of maintenance of margins of safety.

A capital gains preference is often justified as a stimulus to risk taking. As such, the preference should probably be limited to unexpected gains that are attributable to the bet element in financial instruments.<sup>169</sup> Yet, to address revenue loss and inefficiencies associated with tax-avoidance transactions, gain or loss attributable to the bet element in derivative financial instruments, as well as debt,<sup>170</sup> can be subjected to noncapital treatment, leaving any capital gains preference to apply to shares that combine an expected time-value return with a substantial bet element.<sup>171</sup> Here again, an income tax system can defensibly distinguish between shares of closely-held and widely-held corporations in its effect on risk taking. As already emphasized above in Part IV.B, a possible equity capital market bias in the context of closely-held corporations can be addressed by provision of a lower rate of corporate tax that encourages retention of earnings. A capital gains preference that is limited to shares of such corporations can be seen to reinforce this incentive effect. With shares of widely-held corporations, there is no such bias and full taxation of realized gains could suppress some of the churning that is characteristic of speculative trading, without significantly diminishing the price revelation and

---

<sup>169</sup> See *e.g.*, William D. Popkin, *The Deep Structure of Capital Gains*, 33 CASE WES. RES. L. REV. 153 (1983) (arguing that the distinction between expected and unexpected gains and losses distinguishes time-value returns from returns to risk taking and the associated bet element that is the target of a capital gains preference provided as a stimulus to risk taking).

<sup>170</sup> See *e.g.*, Eddins, *supra* note 5 (arguing that different tax rates of capital market participants produce incentives that contribute strongly to financial instability).

<sup>171</sup> See TIM EDGAR, THE INCOME TAX TREATMENT OF FINANCIAL INSTRUMENTS: THEORY AND PRACTICE 101-06 (2000) [hereinafter EDGAR, TAX TREATMENT OF FINANCIAL INSTRUMENTS].

liquidity functions provided by public trading.<sup>172</sup> But a tax bias in favor of retention can also be seen as desirable if suppression of excessive leverage and promotion of maintenance of margins of safety is the paramount policy goal. In fact, when the policy goal is reframed in this manner, a capital gains tax preference - just like a corporate/shareholder tax-rate gap - can be supported equally for shares of closely-held and widely-held corporations. In terms of rate choice, a capital gains tax rate for shares that approximates the dividend tax rate can preserve the positive features of a retention bias while avoiding the creation of tax-avoidance opportunities in the form of dividend-stripping transactions.<sup>173</sup>

Even with a preferential tax rate for share gains, an element of double taxation remains under dividend imputation systems because of a general failure to integrate the corporate and shareholder-level taxes when retained earnings are reflected in the value of shares realized on a disposition in the secondary market.<sup>174</sup> In short, limitation of imputation regimes to dividend distributions means that an element of double taxation arises similar to that under classical corporate income tax systems. However, any efficiency losses associated with this element of double taxation are uncertain. By providing a credit for corporate income tax paid, imputation systems maintain the integrated treatment of dividend distributions, which reduces the double

---

<sup>172</sup> See e.g., Krever & Brooks, *supra* note 168, at 82-84 (arguing that any adverse effects on risk taking may be offset by the substantial presence of tax-exempt investors, such as pension funds and venture capital corporations, that benefit from significant tax preferences and provide an adequate supply of risk capital at prices that do not exceed the risk-adjusted opportunity cost of capital). See also Alan J. Auerbach, *Capital Gains Taxation and Tax Reform*, 41 NAT'L. TAX J. 391 (1989); and Daniel Halperin, *A Capital Gains Preference is not EVEN a Second-Best Solution*, 48 TAX L. REV. 381, 385-87 (1993) (emphasizing that a lower capital gains tax rate may only alter the pattern of ownership or allocation of financial assets and not the overall level of investment, with no serious inefficiencies for the economy as a whole).

<sup>173</sup> See e.g., Mintz & Richardson, *supra* note 135, at 398 (emphasizing the need to maintain consistency of dividend and capital gain tax rates on shares).

<sup>174</sup> By permitting the addition of a proportionate share of retained earnings to cost basis, Norway was a notable exception in the extension of its dividend imputation regime to secondary market transactions in shares of widely-held corporations. See Sorensen, *supra* note [128](#), at 567.

taxation of the distributed income.<sup>175</sup> Where the distributed income has previously been taxed as a gain realized on a disposition of the relevant shares, a corresponding loss attributable to the dividend distribution will arise. To the extent that recognition of the loss is permitted,<sup>176</sup> the amount can be considered to effectively offset the prior gain, thereby eliminating any double taxation. Although this offset is far from complete, it at least reduces the incidence of double taxation. Perhaps more importantly, any double taxation that ultimately arises because of the imposition of unintegrated corporate and shareholder-level income taxes on a secondary-market transfer may be an overstated cause of efficiency losses, with any such losses compensated for by a tax bias in favor of retention as a means to promote maintenance of margins of safety.

## V. LOSS LIMITATIONS AND RISK TAKING

As a stimulus to risk taking, the provision of a capital gains preference presumes the presence of a market failure that results in an inadequate pool of risk capital. There is no clear evidence, however, that the level of risk capital is deficient or that any discrimination in the tax system against such investment by taxable investors causes a shortfall.<sup>177</sup> It may instead be the case that, in combination with an unrestricted interest expense deduction, a capital gains tax preference results in excessive risk taking in capital markets. In fact, Minsky's financial instability hypothesis, along with the mismeasurement of risk in capital markets, suggests that a lower capital gains tax rate may exacerbate such behavior even in the presence of:

---

<sup>175</sup> See Leonard E. Burman, *Taxing Capital Gains in Australia: Assessment and Recommendations*, in AUSTRALIAN BUSINESS TAX REFORM IN RETROSPECT AND PROSPECT 113, 123 (Chris Evans & Rick Krever eds., 2009) [hereinafter Burman, *Taxing Capital Gains in Australia*] (observing that dividend imputation credits attributable to retained earnings should be capitalized in the value of shares that are traded in an active secondary market).

<sup>176</sup> Various rationales for limitations on the recognition of losses generally on financial instruments are discussed *infra* in Part V.

<sup>177</sup> The seminal literature survey remains Agnar Sandmo, *The Effects of Taxation on Savings and Risk Taking*, in HANDBOOK OF PUBLIC ECONOMICS 265 (Alan J. Auerbach & Martin Feldstein eds., 1985) (concluding that there is no conclusive basis to tax risky assets inconsistently with riskless assets).

- a reduced recognition rate for capital losses reflecting the reduced inclusion rate for capital gains; and
- a restriction on the deductibility of capital losses to the amount of realized capital gains as a response to the problem of selective realization.

Each of these features effectively increases the after-tax value of capital losses such that deviation from the expected return associated with an asset is increased and, hence, the associated risk. As posited in the taxation and risk taking literature, the attractiveness of risky investments is reduced, which is presumed to result in a suboptimal level of risk taking. But various features of markets for financial assets emphasized by Minsky's financial instability hypothesis suggest that the increased after-tax return from a lower capital gains tax rate may exert a much stronger pull in the direction of increased risk taking than the push of increased after-tax losses in the other direction.<sup>178</sup>

In the wake of the recent credit crisis, the IMF paper notes only the ambiguous effect that certain tax features such as a capital gains preference can have on asset prices;<sup>179</sup> it also briefly reviews the possible effects of the treatment of losses on risk taking,<sup>180</sup> suggesting that limitations on loss deductibility, as well as the application of progressive personal tax rates, can act to suppress it. Consistent with the other limited tax-policy literature,<sup>181</sup> the IMF paper observes that this effect may be desirable where an unspecified set of nontax factors leads to

---

<sup>178</sup> See e.g., Slemrod, *supra* note 5, at 390 (observing that preferential treatment of capital gains dominates when excessively optimistic investors do not account for restricted recognition of capital losses). See also Burman, *Taxing Capital Gains in Australia*, *supra* note 175, at 120 (noting that it is unclear whether a rate preference is required, in addition to the deferral benefit from taxation of capital gains on a realization basis, to offset the increase in the after-tax value of losses because of incomplete offset).

<sup>179</sup> IMF, CRISIS-RELATED ISSUES, *supra* note 5, at 31-33 (concluding that "... structural tax policy is best guided by the core objective of neutrality across assets and over time.").

<sup>180</sup> IMF, CRISIS-RELATED ISSUES, *supra* note 5, at 28-29.

<sup>181</sup> See *supra* note 5.

excessive risk taking. This Part attempts to fill in much of the reasoning supporting this position. It is at least plausible that capital loss quarantining and a reduced recognition rate for capital losses are insufficient to suppress excessive risk taking. Corrective tax policy may require full taxation rates applicable to gains on financial instruments and a combination of:<sup>182</sup>

- tighter loss limitations applicable to such instruments; and
- comprehensive interest expense deductibility restrictions under the personal income tax as a form of loss limitation.

#### A. DOMAR-MUSGRAVE AND THE TAXATION AND RISK TAKING LITERATURE

Any discussion of the effect of taxation on risk taking begins with the model articulated over 60 years ago by Evsey Domar and Richard Musgrave.<sup>183</sup> Under the simple Domar-Musgrave model, portfolio choice is limited to two assets:

- an asset without default risk yielding no real return; and
- a risky asset in the sense that its payoff depends on a specified contingency.

To illustrate the fundamental insight of the model, assume that a risky asset is acquired at a cost of \$100 and has a 50 percent chance of paying \$120 or a 50 percent chance of paying \$80. The expected return is zero ( $[0.5 \times \$20] - [0.5 \times (-\$20)]$ ), which is consistent with the expected return on an alternative riskless asset. Investors determine the composition of their portfolios

---

<sup>182</sup> As a means to reinforce a retention bias and maintenance of margins of safety, share gains could be excluded from noncapital treatment and subject to a preferential tax rate approximating the rate on dividends. *See supra* notes 168-76 and accompanying text. This rationale would not extend to short sales. *But see* Michael R. Powers, David M. Schizer, & Martin Shubik, *Market Bubbles and Wasteful Avoidance: Tax and Regulatory Constraints on Short Sales*, 57 TAX L. REV. 233, 262-63 (2004) (noting that a preferential tax rate for long positions in shares, even where it is justified as a means to alleviate the double taxation of corporate equity income, might be extended to short sales to constrain upward price pressure).

<sup>183</sup> Evsey Domar & Richard Musgrave, *Proportional Income Taxation and Risk Taking*, 58 Q.J. ECON. 388 (1944). *But see also* Joseph E. Stiglitz, *The Effects of Income, Wealth, and Capital Gains Taxation on Risk Taking*, 83 Q.J. ECON. 263 (1969); and James Tobin, *Liquidity Preference as Behavior Towards Risk*, 25 REV. ECON. STUDIES 65 (1958).

based on their taste for risk. Symmetrical treatment of losses and gains ensures that the after-tax gain/loss ratio is the same as the pre-tax ratio. For example, at a 40 percent tax rate, the positive payoff would be \$12, and the negative payoff would be (\$12) (assuming refundability of losses for income tax purposes at the 40 percent rate). In effect, the government shares at the same tax rate in both gains and losses on the risky asset. By lowering the variance of possible payoffs, symmetrical taxation of gains and losses reduces risk associated with the risky asset and may induce a portfolio shift out of the riskless asset. However, an income effect may dominate the substitution effect,<sup>184</sup> with the government effectively serving a risk-bearing function through the tax system. In this respect, recent consumption tax literature<sup>185</sup> has emphasized the income effect and, in particular, the ability of taxpayers to eliminate the taxation of the return to risk-bearing by scaling up their risky asset positions to maintain the variance associated with their pre-tax positions.<sup>186</sup>

---

<sup>184</sup> See Terrence R. Chorvat & Gavin Elkins, *The Effect of the Taxation of Risky Income on Investment Behavior* (Faculty of Law, University of Toronto, The James Hausman Tax Law and Policy Workshop Series October 2009) (laboratory experiment with university students as subjects indicates no scaling up in the presence of symmetrical taxation of gain and loss and likely scaling down).

<sup>185</sup> If taxpayers can freely adjust their investment portfolios to maintain the same pre-tax return on risky assets, only the normal or riskless rate of return may be exempted under a consumption tax and taxed under an income tax. The same proposition may extend to the risk premium for undiversifiable risk. See Joseph Bankman & Barbara H. Fried, *Winners and Losers in the Shift to a Consumption Tax*, 86 GEORGETOWN L.J. 539 (1998); Joseph Bankman & Thomas Griffith, *Is the Debate Between an Income Tax and a Consumption Tax A Debate About Risk? Does it Matter?* 47 TAX L. REV. 377 (1992); Alvin C. Warren, Jr., *How Much Capital Income Taxed Under an Income Tax Is Exempt Under a Cash Flow Tax?* 52 TAX L. REV. 1 (1996); and David A. Weisbach, *The (Non) Taxation of Risk*, 58 TAX L. REV. 1 (2004). The model on which this literature is based is articulated in Louis Kaplow, *Taxation and Risk Taking: A General Equilibrium Perspective*, 47 NAT'L. TAX J. 789 (1994). See also Jeremy I. Bulow & Lawrence H. Summers, *The Taxation of Risky Assets*, 92 J. POL. ECONOMY 20 (1984); and Roger H. Gordon, *Taxation of Corporate Capital Income: Tax Revenues Versus Tax Distortions*, 100 Q.J. ECON. 1 (1985).

<sup>186</sup> See Thomas J. Brennan, *Certainty and Uncertainty in the Taxation of Risky Returns* (New York University School of Law Colloquium on Tax Policy and Public Finance, April 2009) (observing that symmetric taxation of the return to risky assets provides a tax payoff profile equivalent to that of a forward contract written on the underlying asset in an amount equal to the tax that can be eliminated by entering into an equal and opposite forward contract).

By introducing asymmetric taxation of gain and loss on risky assets, limitations on loss deductibility alter the after-tax gain/loss ratio as compared to the pre-tax ratio.<sup>187</sup> If, for example, losses are not recognized while gains are taxed at 40 percent, the after-tax amount of the negative payoff on the risky asset in the above example is the same as its pre-tax amount of \$20; yet the after-tax amount of the positive payoff is \$12. With the gain/loss ratio altered in this particular direction, investors may substitute the riskless asset for the risky asset. Common features of tax systems, such as loss limitations and progressive personal tax rates, introduce asymmetric treatment of gains and losses, which negates the ability to scale the magnitude of the bet element associated with risky assets. Where the income effect dominates, governments are able to tax returns to risk.<sup>188</sup> Where the substitution effect dominates, risk taking is adversely affected, with possible efficiency losses attributable to the shift away from risky assets.

---

<sup>187</sup> Asymmetric taxation of gains and losses can also be a function of the application of progressive personal income tax rates. See Shaviro, *Financial Crisis*, *supra* note 5, at 13 (suggesting that a progressive tax rate structure is the principal source of asymmetric taxation for individual entrepreneurs, while loss limitations are the principal source for large publicly-traded corporations). The extent that loss limitations are binding, and thereby result in asymmetric taxation of gains and losses, may differ under the personal income tax and the corporate income tax. See e.g., Alan J. Auerbach, Leonard E. Burman, & Jonathan M. Siegel, *Capital Gains Taxation and Tax Avoidance: New Evidence from Panel Data*, in DOES ATLAS SHRUG? THE ECONOMIC CONSEQUENCES OF TAXING THE RICH 355, 377-78 (Joel Slemrod ed., 2000) (finding that most individuals in the United States were able to deduct capital losses within one or two years of realization given the ability to deduct up to \$3,000 of such losses annually against ordinary income); Alan J. Auerbach, *Why Have Corporate Tax Revenues Declined? Another Look*, 53 CESIFO ECON. STUDIES 153 (2007) (finding that nondeductible current losses net of net operating losses in the corporate sector increased from 11 percent of income in 1996-97 to 44 percent in 2001-03); Rosanne Altshuler & Alan J. Auerbach, *The Significance of Tax Law Asymmetries: An Empirical Investigation*, 105 Q.J. ECON. 61 (1990) (finding for the period 1971-82 that one-half of firms in the nonfinancial sector, weighted by book assets, were required to carry forward tax benefits); and Michael Cooper & Matthew Knittel, *Partial Loss Refundability: How Are Corporate Tax Losses Used?* 59 NAT'L. TAX J. 651 (2006) (finding for a dataset of firms for the period 1993-2003 that (i) 50-60 percent of tax losses are used over a ten-year carryover period; and (ii) 25-30 percent of tax losses expire unused).

<sup>188</sup> See Reuven Avi-Yonah, *Risk, Rents, and Regressivity: Why the United States Needs Both an Income Tax and a VAT*, 105 TAX NOTES 1651 (2004).

In fact, loss limitations and progressive personal income tax rates have much the same effect as transaction costs and other nontax factors that constrain scaling as well as the substitution effect.<sup>189</sup> Deborah Schenk argues, for example, that the imputation of interest at the riskless rate on all capital assets (including shares) is normatively desirable as a tax base, since the return to risk is taxed only accidentally under an income tax when nontax factors constrain the ability to alter portfolios in response to the tax.<sup>190</sup> However, loss limitations have independent normative significance under an income tax and have generally been seen by tax policymakers to trump possible efficiency losses associated with any behavioral response to asymmetric tax rates for gains and losses. Moreover, the taxation and risk taking literature assumes that risk is accurately priced, in which case the application of asymmetric rates can induce a behavioral response with efficiency losses. As emphasized in Part II.B, the dynamics of financial markets, along with incomplete risk-modeling techniques, have destabilizing consequences. In this environment, loss limitations can also be justified as a constraint on excessive risk taking.<sup>191</sup> But even ignoring the quantitative targeting problem attributable to an inability to calibrate the amount of any corrective tax, the use of loss limitations to moderate risk taking presents a difficult qualitative targeting issue. In particular, it is necessary to distinguish between different types of losses for income tax purposes, since not all losses are attributable to risk taking.<sup>192</sup> A

See also Lawrence Zelenak, *The Sometimes-Taxation of the Returns to Risk-Bearing Under a Progressive Income Tax*, 59 SMU L. REV. 879 (2006) (emphasizing the erratic taxation of risk under progressive tax rates). But see Brennan, *supra* note 186 (demonstrating that asymmetric treatment of risky returns produces tax burdens that are both systematic and quantifiable).

<sup>191</sup> IMF, CRISIS-RELATED ISSUES, *supra* note 5, at 28-29.

<sup>192</sup> See Thomas Abhayaratna & Shane Johnson, *Revisiting Tax Losses*, 24 AUSTL. TAX F. 59, 64-66 (2009); Michael J. McIntyre, *Identifying Tax Losses Entitled to Full Loss Offsets in a Business Profits Tax*

defensible distinction may also be drawn between losses that are attributable to risk taking in the market for consumer goods and services and the same type of losses incurred in financial markets. As a constraint on excessive risk taking, the case for tight loss limitations is strongest in the latter setting, subject to an important exception for a hedge-accounting regime.

The standard rationale for loss limitations is the revenue cost that refundability would entail. The more nuanced version of this rationale depends on the cause of the loss. For this purpose, losses may be characterized as within one of the following general types:<sup>193</sup>

- economic losses attributable to risk taking;
- tax losses attributable to the provision of tax expenditures or preferences for particular types of investment or activities;
- income mismeasurement losses attributable to income inclusion or expense deduction features that are adopted for compliance cost or administrative reasons; and
- tax-avoidance losses and/or fraudulent activity losses attributable to tax-avoidance transactions intended to create or transfer the loss and/or fraudulent reporting of revenue or expense.

Loss limitations within the third and fourth categories can be used to protect the revenue where, respectively, income measurement rules cannot be improved or anti-avoidance provisions and enforcement measures targeting tax avoidance and/or tax evasion are incomplete.<sup>194</sup> Limitations on losses within the first and second categories may be chosen as an alternative to refundability because of the associated revenue cost.<sup>195</sup> With tax losses attributable to the

<sup>193</sup> Abhhayaratna & Johnson, *supra* note 192, at 64-66; and Poddar & English, *supra* note 192, at 492-96.

<sup>194</sup> Abhhayaratna & Johnson, *supra* note 192, at 65.

<sup>195</sup> *Ibid.*

provision of tax expenditures, the value of the particular tax expenditure is reduced, but presumably on the basis of an assessment that the amount of any forgone efficiency gains attributable to the behavioral response otherwise intended to be induced by the tax-expenditure program are less than the revenue saved by limiting the cost of the program. With economic losses attributable to risk taking, any associated efficiency losses are presumably seen to be less than the revenue saved by a rejection of refundability.

McIntyre argues<sup>196</sup> that the adoption of broad loss limitations applicable equally across losses within all four of these general categories is required in the absence of an ability to identify and prohibit the deduction of losses that are attributable to income mismeasurement or tax avoidance/fraudulent activity. This identification problem leaves tax policymakers with the choice of selective refundability, either full or partial, for economic and tax losses arising in specified circumstances or in connection with specified activities. For example, tax-expenditure programs, such as preferential treatment for expenditures on basic research, are often delivered in the form of refundable tax credits. Alternatively, losses generated with accelerated recognition of capital expenses may be permitted to be flowed through to investors for recognition. These exceptions to less than full refundability of expenses enhance the value of the relevant program where such enhancement is considered desirable. It is much more difficult, however, to extend full loss refundability beyond these kinds of specified expenditure programs without also providing recognition of losses attributable to income mismeasurement and tax-avoidance/fraudulent activity.

This identification exercise emphasized by McIntyre is arguably altered where limitations on the recognition of risk-based losses are justified as a means to dampen excessive risk taking. Under this very different rationale, limitations on such losses serve as a form of corrective taxation that is intended to induce a portfolio shift away from risky assets. Indeed, the behavioral response that is assumed to be suboptimal in the taxation and risk taking literature

---

<sup>196</sup> McIntyre, *Identifying Tax Losses*, *supra* note 192.

becomes a desirable effect of limitations on economic losses, presumably on the basis that risk is otherwise mismeasured or, as suggested by Minsky's financial instability hypothesis, investors reduce margins of safety as they increasingly take on leverage in an environment of rising asset prices and profits. But as noted already, operationalizing this particular rationale for the application of limitations on the recognition of risk-based losses may require a distinction to be drawn between the incurrence of these losses in the market for consumer goods and services and those losses incurred in capital markets. The former may provide the best case for the empirical assumption in the taxation and risk taking literature that asymmetric treatment of gains and losses attributable to the imposition of loss limitations imposes efficiency losses attributable to the substitution effect. In effect, risk associated with investments in the real economy is often undiversifiable, and the case is strongest for the government to act as a risk bearer through the provision of either loss refundability or carryover with an interest gross up to preserve the full value of any loss.<sup>197</sup> Tax policymakers must still exercise judgment that any efficiency gains warrant the associated revenue loss and the potential for inappropriate recognition of losses

---

<sup>197</sup> See e.g., Alan J. Auerbach, *Notes on Taxation and Risk Taking*, 24 AUSTL. TAX F. 31, 34 (2009) [hereinafter Auerbach, *Notes*] (observing that government could potentially improve diversification by providing the equivalent of insurance through the tax system for assets that are traded in limited markets); Shaviro, *Financial Crisis*, *supra* note 5, at 15 ("Thus, one could plausibly surmise that the main risk-discouraging effects of nonrefundability relate to risk-taking that has greater social merit, such as that by entrepreneurs establishing start-up companies in which the players will largely bear their own losses rather than passing them onto others in the manner of 'too-big-to-fail' financial institutions."); and Michael P. Devereux & Clemens Fuest, *Is the Corporation Tax an Effective Automatic Stabilizer?* 62 NAT'L. TAX J. 429 (2009) (arguing that more generous treatment of losses would help to smooth the effect of investment shocks to corporate income and thereby enhance the corporate income tax as an automatic stabilizer). See also Michael G. Cooper & Matthew J. Knittel, *The Implications of Tax Asymmetry for U.S. Corporations*, 63 NAT'L. TAX J. 33 (2010) (finding for the period 1993-2004 that partial loss refundability disproportionately affects certain industries and younger firms); and Joseph J. Thorndike, *Risky Business: Using Taxes to Insure Against Loss*, 125 TAX NOTES 9 (2009) (describing post-World War I proposal for delivery of business loss insurance through the income tax system). But see Julie Berry Cullen & Roger H. Gordon, *Taxes and Entrepreneurial Risk-Taking: Theory and Evidence for the U.S.*, 91 J. PUB. ECON. 1479 (2007) (finding that various tax-law features, including loss limitations and progressive personal rates, have collectively had large effects on the amount of entrepreneurial activity, but observing that the option to incorporate can encourage risk taking by providing favorable asymmetric rates where the corporate rate is lower than the personal rate).

attributable to income mismeasurement and/or tax-avoidance/fraudulent activity. In this respect, forms of limited loss refundability tend to be targeted to the small business sector where shares and debt of issuers are not traded in deep and liquid markets, and investors bear undiversifiable risk attributable to the payoff profiles and value of the underlying assets.<sup>198</sup> Moreover, transaction costs and incomplete markets mean investors cannot scale their investments in risky assets, and governments collect tax on the returns to risk.

These same conditions do not hold with financial instruments traded in deep and liquid markets. Unique risk can be diversified, and scaling up the magnitude of a bet is more readily possible, particularly with derivative financial instruments.<sup>199</sup> Despite the lack of any definitive empirical evidence,<sup>200</sup> limitations on the recognition of economic losses may be invoked as a

---

<sup>198</sup> See e.g., ITA, paragraph 3(d) and the definitions of “business investment loss” in ITA, paragraph 39(1)(c), “allowable business investment loss” in ITA, paragraph 38(c), and “noncapital loss” in ITA, subsection 111(8), which together provide noncapital loss treatment for the recognized portion of a capital loss portion realized on shares and debt of “small business corporations.” Such treatment is reported as a tax expenditure in the Canadian government’s tax-expenditure accounts. *But see* Boadway, *supra* note 134, at 125 (arguing that provisions facilitating loss offsetting should be reported as memorandum items and not tax expenditures).

<sup>199</sup> See Auerbach, *Notes, supra* note 197, at 34 (the ability to scale a position is a reasonable assumption for liquid assets traded in established markets but may not be as reasonable for family businesses). See also Geanakoplos, *Leverage Cycle, supra* note 34, at 6 (emphasizing the scaling that occurred with the standardization of credit default swaps, which facilitated leveraging of pessimistic views of the subprime mortgage market); Rosenzweig, *supra* note 14 (assuming scaling of bets with derivatives in response to taxation of the return to risk); and David M. Schizer, *Balance in the Taxation of Derivative Securities: An Agenda for Reform*, 104 COLUM. L. REV. 1886 (2004) (observing that scaling is largely unconstrained with derivatives that are pure bets giving rise to unexpected gain or loss).

<sup>200</sup> See Chorvat & Elkins, *supra* note 184, at 6 (noting the data difficulties which make empirical testing of the substitution effect difficult); Shaviro, *Financial Crisis, supra* note 5, at 3 (“Yet there is little evidence that nonrefundability or graduated rates mattered greatly to the managers who were taking absurd risks on behalf of publicly traded companies ...”); and Weisbach, *supra* note 185, at 45-47 (surveying the empirical literature on taxation and portfolio choice and characterizing it as inconclusive). *But see* Eddins, *supra* note 5, at 16-21 (arguing that credit default swaps permitted the stripping of credit risk and its tax-driven transfer to those investors with symmetric gain and loss tax rates). The irrelevance of tax as a factor in the scaling of bets may be inferred from the investment behavior of tax-exempt fund managers who have aggressively pursued trading strategies designed to produce supernormal returns. See e.g., PHILIP AUGAR, CHASING

means to moderate excessive risk taking attributable to scaling, which can have systemic risk implications when the instability-breeding dynamics of financial markets are exacerbated by the mismeasurement of risk or other failures of risk management.<sup>201</sup> In the absence of any behavioral response to loss limitations that would moderate exposure to systemic risk, government must assume a role of insurer by acting as lender of last resort and propping up asset values and profits by stimulating demand in a downturn. The application of loss limitations in publicly-traded asset markets, where diversification is otherwise available and scaling can more readily eliminate taxation of risk, can be defended as a form of insurance premium<sup>202</sup> that is extracted by government for already serving these risk-bearing roles as lender of last resort and provider of aggregate demand in an economic downturn. In short, it is not clear that government needs to serve an additional risk-bearing role through the provision of loss refundability in this market.<sup>203</sup> Serving such a risk-bearing function may even exacerbate market failures that are the source of excessive risk taking. Although the same result may be attributable to the government's other risk-bearing functions, those functions must be filled by government because of the absence of any comparable market institution.<sup>204</sup> This is not the case with investment in risky assets where

---

ALPHA: HOW RECKLESS GROWTH AND UNCHECKED AMBITION RUINED THE CITY'S GOLDEN DECADE 75-95 (2009); and BERNSTEIN, *EVOLVING*, *supra* note 46, at 148-64. *But see also* Jack Mintz & Michael Smart, *Tax-Exempt Investors and the Asset Allocation Puzzle*, 83 J. PUB. ECON. 195 (2002) (arguing that consumption tax treatment of pension funds provides the equivalent of the front loading of loss refundability and explains the holding of risky equities).

<sup>201</sup> See Stulz, *Risk Management Failures*, *supra* note 55. See also Chorvat & Elkins, *supra* note 184, at 20 (speculating that investment professionals may be more likely to engage in tax-driven scaling).

<sup>202</sup> See e.g., Brennan, *supra* note 186 (analogizing asymmetric treatment of the return to a risky asset as equivalent to the payoff profile associated with an option written on the asset, with carryover of pricing models based on the cost of synthetic replication of the option equal to the tax on the underlying asset).

<sup>203</sup> *But see* Terrence R. Chorvat, *Apologia for the Double Taxation of Corporate Income*, 38 WAKE FOREST L. REV. 239 (2003) (arguing that deadweight loss attributable to the classical corporate income tax can be offset by the provision of full loss offset in respect of portfolio equity).

<sup>204</sup> See DAVID A. MOSS, *WHEN ALL ELSE FAILS: GOVERNMENT AS THE ULTIMATE RISK MANAGER* (2002).

deep and liquid markets provide a broad range of self-insurance opportunities through portfolio diversification.

As a form of loss limitation, a prohibition on the recognition of losses on derivative financial instruments, as well as traded debt and shares, would be the strongest policy instrument intended to correct market failure in the form of excessive risk taking or, alternatively, to limit the extent of publicly-provided insurance in capital markets. Complete nonrecognition of such losses could inappropriately constrain, however, the price revelation and liquidity functions of these markets, with offsetting efficiency losses.<sup>205</sup> A weaker response would be limitation of the deduction of unexpected losses attributable to the bet element in the same set of instruments to the amount of any unexpected gains that are similarly attributable to the bet element in such instruments. This form of limitation is comparable to that for capital losses under a realization-based capital gains tax system with less than full recognition rates, and is required to the extent that gains and losses are treated on noncapital account.<sup>206</sup> A defensible case can also be made for the use of this kind of broad limitation as an alternative to comprehensive marking-to-market as a response to the problem of selective realization. For the most part, existing legislative regimes do

---

<sup>205</sup> The necessary balance between the price revelation and liquidity functions, on the one hand, and constraint of excessive risk taking, on the other hand, is similar to much the same balance emphasized in the literature on financial transaction taxes. *See e.g.*, Matheson, *supra* note 14.

<sup>206</sup> To the extent that traded shares are subject to a lower tax rate approximating the dividend tax rate, losses on such shares could be quarantined against gains. Noncapital losses associated with the proprietary trading operations of a financial institution could be quarantined against gains from those operations where such operations are permitted for regulatory purposes. *See e.g.*, THE TURNER REVIEW, *supra* note 55, at 93-96 (criticizing the case for a prohibition on proprietary trading by banks with access to retail deposit insurance and lender-of-last resort facilities). But see also Adair Turner, Chairman, Financial Services Authority, *What Banks Do, What Should they Do and What Public Policies Are Needed to Ensure Best Results for the Real Economy?* (Cass Business School, March 17, 2010), available at [http://www.fsa.gov.uk/Pages/Library/Communication/.../0317\\_at.shtml](http://www.fsa.gov.uk/Pages/Library/Communication/.../0317_at.shtml) (arguing that market liquidity is beneficial only to a point, and capital requirements should be used to limit the extent of proprietary trading by commercial banks). Hedge funds organized in partnership form would not be able to flow through such losses to be recognized by partners against other income. Because tax exemptions are unaffected by loss limitations, it may be necessary to use investment allocation rules to moderate the destabilizing effects of trading strategies.

not rely on marking-to-market as the principal response to selective realization; nor do they reflect a well-targeted approach based on liquidity as a proxy for instruments that can be strategically traded because of low transaction costs.<sup>207</sup> A rule limiting the deduction of risk-based losses against risk-based gains on financial instruments is seen in some of the tax-policy literature as a means to address the problem of selective realization, albeit at the expense of a potentially adverse impact on risk taking attributable to asymmetric recognition rates.<sup>208</sup> However, as a policy instrument intended to moderate risk taking in deep and liquid markets for financial instruments, any form of broad loss limitation rule would remain binding even if comprehensive mark-to-market reporting were applied to such instruments as a response to the problem of selective realization.<sup>209</sup>

An important exception from a tighter noncapital loss limitation applied to financial instruments as the functional equivalent of a corrective tax on risk taking can be made for those instruments that are used as to hedge positions in nonfinancial assets.<sup>210</sup> Taxing a hedge with reference to an underlying position ensures matching of both character and timing of gain and

---

<sup>207</sup> See EDGAR, TAX TREATMENT OF FINANCIAL INSTRUMENTS, *supra* note 171, at 228-39.

<sup>208</sup> See *e.g.*, Robert H. Scarborough, *and the Design of Loss Limitations Under a Realization-Based Income Tax*, 48 TAX L. REV. 677 (1993) *Risk, Diversification* (discussing various types of deductibility restrictions and their possible effects). See also Brooks & Krever, *supra* note 168, at 117-22 (discussing the role and design of capital loss limitations generally). A broad loss limitation might also eliminate any carry back provision as a tax incentive to sell financial assets with accrued losses in a debt deflationary environment. See *e.g.*, Slemrod, *supra* note 5, at 391 (noting the “lock out” effect: that is, the inducement to sell assets with accrued losses to offset against previously realized gains).

<sup>209</sup> Mark-to-market reporting is applied to traders or dealers largely because they do not face the same kind of liquidity constraint as other taxpayers, which is the standard argument for application for realization-based recognition. See Edward D. Kleinbard & Thomas L. Evans, *The Role of Mark-to-Market Accounting in a Realization-Based Tax System*, 75 TAXES 788 (1997) (characterizing the application of mark-to-market reporting to the inventory of traders or dealers as a substitute for a hedge-accounting regime).

<sup>210</sup> The same exception could be extended to hedges of shares taxed at a lower rate consistent with the tax rate on dividends as a means to reinforce a retention bias and promote maintenance of margins of safety. See *supra* notes 168-176, and accompanying text.

loss on the offsetting positions. By maintaining symmetry of effective tax rates, adverse pricing effects that might otherwise inhibit efficient hedging strategies are avoided.<sup>211</sup> In effect, because they are risk-reducing transactions, hedge transactions can be excluded from a tighter loss limitation rule as a means to reinforce the dampening effect provided by maintenance of margins of safety.<sup>212</sup>

Another possible exception would provide some form of targeted loss refundability as a means to allow financially-distressed corporations to restructure.<sup>213</sup> As one possible example, Canada allows financially-distressed corporations to use accumulated tax losses to lower their after-tax cost of financing by replacing outstanding debt held by arm's-length creditors with preferred shares ("distress preferred shares") paying tax-sheltered dividends.<sup>214</sup> Nonetheless, the rationale for this tax expenditure program, as well as the specifics of its targeting, is problematic. Perhaps most importantly, no attempt is made to limit the program to those corporations whose failure would entail systemic risk. The broader availability of the program suggests that it can be supported more defensibly as a means to alleviate "congestion externalities" otherwise associated with the mass layoff of employees on the failure of a business. Although it has not been the

---

<sup>211</sup> See e.g., Schizer, *supra* note 199, at 1914-15 (arguing that a hedge-accounting regime is defensible because of the maintenance of symmetry of gain and loss recognition rates for offsetting positions).

<sup>212</sup> The need for such an exception has not been the subject of any systematic empirical study in the context of income tax systems that give rise to the worst character and timing mismatches. The conventional view in the finance literature holds that hedging can increase the value of a firm by, in part, reducing taxes through the "smoothing" of taxable income. See e.g., John R. Graham & Clifford W. Smith, Jr., *Tax Incentives to Hedge*, 54 J. FIN. 2241(1999) (exploring the extent to which firms facing convex tax functions hedge to reduce the volatility of taxable income). *But see also* John R. Graham & Daniel A. Rogers, *Do Firms Hedge in Response to Tax Incentives?* 57 J. FIN. 815 (2002) (finding that firms hedge to increase debt capacity and its associated tax benefit).

<sup>213</sup> See e.g., Sullivan, *10 Changes*, *supra* note 11, at 1295-96 (recommending the loosening of restrictions on the use of losses by buyers of financial institutions and other corporations considered "too big to fail," as well as relaxation of tax rules on cancellation of indebtedness).

<sup>214</sup> See Tim Edgar, *Distress Preferred Shares and Small Business Development Bonds: A Tax Expenditure Analysis*, 42 CAN. TAX J. 659 (1994).

subject of any empirical inquiry, any impact on risk taking from the relaxation of the binding nature of loss limitations in these limited circumstances may be weak.<sup>215</sup>

#### B. RESTRICTIONS ON THE DEDUCTION OF INTEREST EXPENSE UNDER THE PERSONAL INCOME TAX AS A FORM OF LOSS LIMITATION

Because the immediate cause of the current credit crisis was a price collapse in the US housing market, it is understandable that the status of the home mortgage interest deduction in that country has attracted attention. When it comes to the personal income tax, it is unsurprising, therefore, that the tax-policy literature highlights tax preferences for housing, including the deductibility of home mortgage interest (or other form of home mortgage tax relief such as a tax credit).<sup>216</sup> Once the housing market recovers, the IMF paper suggests, for example, that countries with such relief consider phasing it out in the absence of the taxation of imputed rental income associated with home ownership.<sup>217</sup> The apparent basis for this recommendation is the perceived need to eliminate a tax bias in favor of household leverage as a source of financial instability in this particular asset market.

It seems reasonably clear, however, that the housing price bubble was fueled primarily by innovative mortgage lending techniques which met an otherwise unsatisfied demand.<sup>218</sup> To a limited extent, the home mortgage interest deduction may have played a secondary role in

---

<sup>215</sup> See IMF, CRISIS-RELATED ISSUES, *supra* note 5, at 29 (suggesting that addressing a debt tax bias attributable to the corporate interest deduction would limit the risks of easing restrictions on the use of tax losses, which may be particularly defensible in the case of bank failure).

<sup>217</sup> *Id.* at 24.

<sup>218</sup> See *e.g.*, Slemrod, *supra* note 5, at 390. See also Hemmelgarn & Nicodeme, *supra* note 5, at 25 (“... tax incentives may have played a role in the development of the housing bubble but the size of this role is difficult to assess, although the odds are that this role has been secondary to monetary policy and credit markets developments.”).

lowering the after-tax cost of financing and feeding this demand,<sup>219</sup> which was met with supply from both domestic and foreign savings through the originate and distribute securitization model. Given this likely limited role of the home mortgage interest deduction, it is surprising that consideration of the relationship between tax policy and financial instability does not go further and discuss restrictions on the deduction of investment interest expense under the personal income tax as a particular form of loss limitation which can similarly constrain excessive risk taking associated with excessive household leverage. This Part broadens the focus on the relationship between tax policy and financial instability to consider the policy case for comprehensive restrictions on the deductibility of interest expense generally under the personal income tax.

As reflected in standard country practice, the case for nondeductibility of home mortgage interest expense is strong where the return from this dual-purpose asset is commonly tax-preferred in the form of the exemption of realized gain and the nontaxation of imputed rental income. In the presence of these tax preferences for this particular asset, the personal consumption element can be taken as dominant and the associated interest expense denied deductibility like any other personal consumption expense. In this respect, tax policymakers in many countries have concluded that any spillover benefits associated with home ownership do not warrant the provision of an additional subsidy in the form of home mortgage interest relief. The contentious issue is, instead, the need for restrictions on the deduction of investment interest expense as a particularized form of loss limitation applicable to expected loss in the form of interest expense rather than unexpected loss attributable to the resolution of a bet element in a financial instrument.<sup>220</sup> In fact, the conventional framing of the policy case for investment interest restrictions is not unlike that for loss limitations generally. Moreover, when the case is

---

<sup>219</sup> The taxable income profiles of borrowers in the subprime mortgage market means that the value of the tax shield from the home mortgage interest deduction is minimal to nonexistent.

<sup>220</sup> See Tim Edgar, *Interest Deductibility Restrictions - Expecting Too Much from REOP?* 52 CAN. TAX J. 1130 (2004).

reframed as an attempt to impose a corrective tax on excessive leverage, the parameters of investment interest expense restrictions are similar to those of the loss limitation rule for financial instruments suggested in the immediately preceding Part V.A.

Interest expense limitations under the personal income tax are conventionally justified in the tax-policy literature as a means to limit the distributional and efficiency effects otherwise associated with income mismeasurement;<sup>221</sup> they target the windfall gains otherwise available from an accrual-based interest expense deduction on borrowed funds used to acquire an asset that generates tax-preferred revenue or gain attributable to either tax-expenditure provisions or structural timing rules. As with loss limitations generally, the strongest case for the application of interest deductibility limitations is provided by straddle transactions, which combine offsetting expected cash flows and are entered into to derive a tax benefit from the inconsistent tax treatment of the short (borrowing) and long (asset acquisition) sides of the transaction. As instances of tax avoidance, these transactions are devoid of any desirable consequential attributes. By restoring consistency of tax treatment of loss and gain associated with the short and long sides of straddle transactions, restrictions on the deduction of interest expense eliminate the tax benefit which is the only reason to enter into such transactions. The necessary assessment of the consequential attributes of an unrestricted interest expense deduction are much more problematic, however, when the focus shifts from straddle transactions to nonstraddle transactions - that is, transactions that are, in part, equity financed such that the expected cash

flows on a long asset acquisition exceed the expected cash flows on an associated short borrowing.

Ignoring legislative design features for the moment, those who are skeptical about the policy case for broadly-based restrictions on the deduction of interest expense under the personal income tax tend to characterize such restrictions as just one specific type of limitation on the recognition of losses.<sup>222</sup> In other words, they highlight a negative consequential attribute of broadly-based restrictions on the interest expense deduction that is, in fact, seen to be characteristic of loss limitations generally: By reducing the tax rate on unexpected losses and thereby increasing the after-tax amount of those losses, a broadly-based loss limitation increases the variance of the after-tax returns on a wide range of affected assets, which can deter investment in those assets. In this respect, there is nothing particularly unique about broadly-based restrictions on the deduction of interest expense. Where a taxpayer borrows funds to acquire an income-earning asset, unexpected loss is realized when the expected cash flows associated with the long asset acquisition do not materialize. Because the unexpected loss is attributable, in part, to interest expense on the short borrowing, a restriction on the deduction of the interest expense can result in an increase of the after-tax amount of the unexpected loss, with a negative impact on risk taking following from the increased variance in after-tax returns that the deductibility restriction causes. Protection of the revenue base, as well as maintenance of an acceptable income distribution and limitation of the cost of tax-expenditure provisions, is thus seen to come at the cost of a potentially adverse impact on risk taking.

Where the target of interest expense restrictions is a range of nonstraddle transactions with consequential attributes that are nonetheless seen to warrant a response, some form of

REV. 15 (1989); and Leandra Lederman, *The Entrepreneurship Effect: An Accidental Externality in the Federal Income Tax*, 65 OHIO ST. L. J. 1401 (2004).

passive loss limitations<sup>223</sup> is the obvious target-effective response. This type of legislative regime relies on the identification of particular income sources (for example, investment income and passively-earned business income) as the core targeting feature. The character of the identified income sources is effectively used as a proxy for the consequential attributes that presumably justify application of the interest deductibility restrictions to straddle transactions and a range of nonstraddle transactions. But if the rationale for interest deductibility restrictions under the personal income tax is reframed as a corrective tax on excessive risk-taking associated with excessive leverage, the case for some form of passive loss limitations arguably becomes that much stronger. Similar to loss limitations generally, the strongest case for the application of such limitations as a restriction on the deduction of interest expense is in the context of asset acquisitions in deep and liquid markets where diversification of risk is readily available and scaling of any bet is possible at low transaction costs.<sup>224</sup> Interest deductibility restrictions as a particularized form of loss limitation ensure that the government does not act as an insurer and collects tax on risk taking; they also may suppress excessive leverage characteristic of speculative and Ponzi finance states and promote maintenance of margins of safety. Indeed, interest deductibility restrictions can support regulatory limitations on leverage, such as margin requirements and minimum levels of equity for mortgage eligibility.

A focus on the type of income source may also be a much better proxy for the application of restrictions as a corrective tax on excessive leverage. In particular, passive sources of income tend to be closely associated with financial assets acquired in deep and liquid markets, which are the most susceptible to excessive risk taking. An exception for income earned in an active business can serve as a proxy for an inability to diversify, in which case the potentially

<sup>224</sup> See e.g., JIM STANFORD, PAPER BOOM: WHY REAL PROSPERITY REQUIRES A NEW APPROACH TO CANADA'S ECONOMY 316 (1999) (suggesting that the deduction of interest expense associated with leveraged share acquisitions should be denied because of the distributional consequences of

adverse effects of interest deductibility restrictions on risk taking are most compelling, and the government should act as a risk bearer. Indeed, even with an unrestricted interest expense deduction in this particular context, full loss refundability is undermined by noncapital loss limitations, which may or may not strike an appropriate balance between the need for a constraint on excessive risk taking associated with an unrestricted interest expense deduction and any adverse impact on risk taking that deductibility restrictions might entail. The same balance need not be struck, however, with investment in the housing market. Although there is not the same ability to diversity risk as there is with deep and liquid markets for financial assets, real estate speculation should be ineligible for an active business exception and thereby subject to interest deductibility restrictions. As the recent credit crisis illustrates all too painfully, investment in this market is especially susceptible to speculative and Ponzi financing.<sup>225</sup>

## VI. CONCLUSION

A focus on moderation of financial instability as a public policy goal requires a comprehensive reexamination of regulatory regimes which are necessarily limited in their application to the supply side of capital markets. Consistent with an emerging literature, this article has suggested some directions in which tax policy can play an important secondary role, particularly on the demand side of capital markets where the effect of regulatory regimes focused on the supply side is indirect. More particularly, tax constraints on leverage, both corporate and

---

the deduction and the inefficiencies that follow from the excessive trading of shares that is induced, in part, by the deduction).

<sup>225</sup> See PRODUCTIVITY COMM., FIRST HOME OWNERSHIP 75-121 (2004) (Austl.) (suggesting that price pressure in the housing sector in Australia has been caused, in part, by the combination of a preferential capital gains tax rate and an unrestricted interest expense deduction on borrowed funds used to acquire rental property). See also Gavin A. Wood & Yong Tu, *Are There Investor Clienteles in Rental Housing?* 32 REAL EST. ECON. 413 (2004) (finding that marginal tax rates affect gross and net rental yields of investors' rental property portfolios); and Turner, *supra* note 206 (arguing that macro-prudential regulatory tools should be designed differently for real estate finance and other forms of finance).

household, can moderate the “animal spirits”<sup>226</sup> that drive capital markets to extremes of optimism. Given various practical policy constraints that necessitate incomplete consistency of the taxation of returns to corporate debt and equity, the article emphasizes how certain of the features of dividend imputation systems can promote maintenance of margins of safety, primarily through a tax bias in favor of the retention of earnings for a range of taxable investors. This bias should be supported, however, by adoption of comprehensive thin capitalization rules intended to constrain the appetite for corporate leverage of tax-exempt and nonresident investors. Limits on the deductibility of interest expense under the personal income tax targeted to investment in the housing market, as well as publicly-traded financial assets, can similarly be justified as necessary tax constraints. In addition, tighter limitations on the recognition of unexpected losses on financial instruments generally, along with full taxation of unexpected gains, can be framed as the equivalent of a tax intended to correct excessive risk taking in the face of its mismeasurement. But given the empirical ambiguity of their effectiveness, such limitations can be supported, alternatively, as a constraint on the extent of the provision of public insurance.
